50

51 **1 INTRODUCTION**

52 The Statistical Data and Metadata Exchange (SDMX) initiative (<http://www.sdmx.org>)
53 sets standards that can facilitate the exchange of statistical data and metadata using
54 modern information technology, with an emphasis on aggregated data.

55
56 There are several sections to the SDMX Technical Specification:

- 57
- 58 1. The SDMX Information Model - the information model on which syntax-specific
59 implementations described in the other sections are based. This document
60 includes as appendixes a UML tutorial and a tutorial for those who are
61 unfamiliar with key families as a way of describing statistical data structures.
62 This document is not normative.
63
 - 64 2. SDMX-EDI - the EDIFACT format for exchange of SDMX-structured data and
65 metadata. This document contains normative sections describing the use of
66 the UN/EDIFACT syntax in SDMX messages. This document has normative
67 sections.
68
 - 69 3. SDMX-ML - the XML format for the exchange of SDMX-structured data and
70 metadata. This document has normative sections describing the use of the
71 XML syntax in SDMX messages, and is accompanied by a set of XML
72 schemas and sample XML document instances. This document has normative
73 sections.
74
 - 75 4. The SDMX Registry Specification provides for a central registry of information
76 about available data and reference metadata, and for a repository containing
77 structural metadata and provisioning information. This specification defines the
78 basic services offered by the SDMX Registry: registration of data and
79 metadata; querying for data and metadata; and subscription/notification
80 regarding updates to the registry. This document has normative sections.
81
 - 82 5. The SDMX Implementor's Guide – this is a guide to help those who wish to use
83 the SDMX specifications. It includes reference material for the use of the SDMX
84 Information Model; a section describing the expressive differences of the
85 various messages and syntaxes; and provides some best practices for
86 assigning identifiers and designing key families. This document is not
87 normative.
88
 - 89 6. Web Services Guidelines – this is a guide for those who wish to implement
90 SDMX using web-services technologies. It places an emphasis on those
91 aspects of web-services technologies (including, but not requiring, an SDMX-
92 conformant registry) which will work regardless of the development
93 environment or platform used to create the web services, and recommends the
94 use of the WS-I version 1.1 specification. This document is not normative.
95

96 **2 CHANGES FROM VERSION 1.0**

97 The 2.0 version of this standard represents a significant increase in scope, and also
98 provides more complete support in those areas covered in the version 1.0
99 specification. Version 2.0 of this standard is backward-compatible with version 1.0, so
100 that existing implementations can be easily migrated to conformance with version 2.0.

101

102 Note that the idea of backward-compatibility in the standards is based on the
103 information model. In this release, some non-backward-compatible changes have
104 been made to the SDMX-ML formats. The same set of information required to use
105 version 1.0 of the specification will permit the use of the same features in the version
106 2.0 specifications, however. Thus, a key family is easily translated from version 1.0 to
107 version 2.0, without requiring any new information regarding structures, etc. There
108 have been no changes to the SDMX-EDI format.

109

110 The changes can be briefly summarized:

111

- 112 • In addition to describing and specifying data structures and formats (along with
113 related structural metadata), the version 2.0 specification also provides for the
114 exchange of metadata which is distinct from the structural metadata in the 1.0
115 version. This category includes “reference” metadata (regarding data quality,
116 methodology, and similar types – it can be configured by the user to include
117 whatever concepts require reporting); metadata related to data provisioning
118 (release calendar information, description of the data and metadata provided,
119 etc.); and metadata relevant to the exchange of categorization schemes.
- 120 • Provision is made in the 2.0 standard for standard communication with registry
121 services, to support a data-sharing model of statistical exchange. These
122 services include registration of data and metadata, querying of registered data
123 and metadata, and subscription/notification.
- 124 • The support for exchange of statistical data and related structural metadata
125 has been expanded. Some support is provided for qualitative data; data cube
126 structures are described; hierarchical code lists are supported; relationships
127 between data structures can be expressed, providing support for extensibility
128 of data structures; and the description of functional dependencies within cubes
129 are supported.

130

131 **3 PROCESSES AND BUSINESS SCOPE**

132 **3.1 Process Patterns**

133 SDMX identifies three basic process patterns regarding the exchange of statistical data
134 and metadata. These can be described as follows:

135

- 136 1. *Bilateral exchange*: All aspects of the exchange process are agreed between
137 counterparties, including the mechanism for exchange of data and metadata,
138 the formats, the frequency or schedule, and the mode used for communications
139 regarding the exchange. This is perhaps the most common process pattern.
- 140 2. *Gateway exchange*: Gateway exchanges are an organized set of bilateral
141 exchanges, in which several data and metadata sending organizations or
142 individuals agree to exchange the collected information with each other in a
143 single, known format, and according to a single, known process. This pattern
144 has the effect of reducing the burden of managing multiple bilateral exchanges
145 (in data and metadata collection) across the sharing organizations/individuals.
146 This is also a very common process pattern in the statistical area, where
147 communities of institutions agree on ways to gain efficiencies within the scope
148 of their collective responsibilities.

149

150

151

3. *Data-sharing exchange*: Open, freely available data formats and process patterns are known and standard. Thus, any organization or individual can use any counterparty's data and metadata (assuming they are permitted access to it). This model requires no bilateral agreement, but only requires that data and metadata providers and consumers adhere to the standards.

152

153

154

155

156

157

This document specifies the SDMX standards designed to facilitate exchanges based on any of these process patterns, and shows how SDMX offers advantages in all cases. It is possible to agree bilaterally to use a standard format (such as SDMX-EDI or SDMX-ML); it is possible for data senders in a gateway process to use a standard format for data exchange with each other, or with any data providers who agree to do so; it is possible to agree to use the full set of SDMX standards to support a common data-sharing process of exchange, whether based on an SDMX-conformant registry or some other architecture.

158

159

160

161

162

163

164

165

166

The standards specified here specifically support a data-sharing process based on the use of central registry services. Registry services provide visibility into the data and metadata existing within the community, and support the access and use of this data and metadata by providing a set of triggers for automated processing. The data itself is not stored in a central registry – these services merely provide a useful set of metadata about the data (and additional metadata) in a known location, so that users/applications can easily locate and obtain whatever data and/or metadata is registered. The use of standards for all data, metadata, and the registry services themselves is ubiquitous, permitting a high level of automation within a data-sharing community.

167

168

169

170

171

172

173

174

175

176

177

It should be pointed out that these different process models are not mutually exclusive – a single system capable of expressing data and metadata in SDMX-conformant formats could support all three scenarios. Different standards may be applicable to different processes (for example, many registry services interfaces are used only in a data-sharing scenario) but all have a common basis in a shared information model.

178

179

180

181

182

183

In addition to looking at collection and reporting, it is also important to consider the dissemination of data. Data and metadata – no matter how they are exchanged between counterparties in the process of their development and creation – are all eventually supplied to an end user of some description. Often, this is through specific applications inside of institutions. But more and more frequently, data and metadata are also published on websites in various formats. The dissemination of data and its accompanying metadata on the web is a focus of the SDMX standards. Standards for statistical data and metadata allow improvements in the publication of data – it becomes more easily possible to process a standard format once the data is obtained, and the data and metadata are linked together, making the comprehension and further processing of the data easier.

184

185

186

187

188

189

190

191

192

193

194

195

In discussions of statistical data, there are many aspects of its dissemination which impact data quality: data discovery, ease of use, and timeliness. SDMX standards provide support for all of these aspects of data dissemination. Standard data formats promote ease of use, and provide links to relevant metadata. The concept of registry services means that data and metadata can more easily be discovered. Timeliness is improved throughout the data lifecycle by increases in efficiency, promoted through the availability of metadata and ease of use.

196

197

198

199

200

201

202

203 It is important to note that SDMX is primarily focused on the *exchange* and
204 *dissemination* of statistical data and metadata. There may also be many uses for the
205 standard model and formats specified here in the context of internal processing of data
206 that are not concerned with the exchange between organizations and users, however.
207 It is felt that a clear, standard formatting of data and metadata for the purposes of
208 exchange and dissemination can also facilitate internal processing by organizations
209 and users, but this is not the focus of the specification.

210 **3.2 SDMX and Process Automation**

211 Statistical data and metadata exchanges employ many different automated processes,
212 but some are of more general interest than others. There are some common
213 information technologies that are nearly ubiquitous within information systems today.
214 SDMX aims to provide standards that are most useful for these automated processes
215 and technologies.

216

217 Briefly, these can be described as:

218

219 1. *Batch Exchange of Data and Metadata:* The transmission of whole or partial
220 databases between counterparties, including incremental updating.

221

222 2. *Provision of Easily Processable Data and Metadata on the Internet:* Internet
223 technology - including its use in private or semi-private TCP/IP networks - is
224 extremely common. This technology includes XML and web services as
225 primary mechanisms for automating data and metadata provision, as well as
226 the more traditional static HTML and database-driven publishing.

227

228 3. *Generic Processes:* While many applications and processes are specific to
229 some set of data and metadata, other types of automated services and
230 processes are designed to handle any type of statistical data and metadata
231 whatsoever. This is particularly true in cases where portal sites and data feeds
232 are made available on the Internet.

233

234 4. *Presentation and Transformation of Data:* In order to make data and metadata
235 useful to consumers, they must support automated processes that transform
236 them into application-specific processing formats, other standard formats, and
237 presentational formats. Although not strictly an aspect of exchange, this type of
238 automated processing represents a set of requirements that must be supported
239 if the information exchange between counterparties is itself to be supported.

240

241 The SDMX standards specified here are designed to support the requirements of all of
242 these automation processes and technologies.

243

244 **3.3 Statistical Data and Metadata**

245 To avoid confusion about which "data" and "metadata" are the intended content of the
246 SDMX formats specified here, a statement of scope is offered. Statistical "data" are
247 sets of often numeric observations which typically have time associated with them.
248 They are associated with a set of metadata values, representing specific concepts,
249 which act as identifiers and descriptors of the data. These metadata values and

250 concepts can be understood as the named dimensions of a multi-dimensional co-
251 ordinate system, describing what is often called a "cube" of data.

252

253 SDMX identifies a standard technique for modelling, expressing, and understanding
254 the structure of this multi-dimensional "cube", allowing automated processing of data
255 from a variety of sources. This approach is widely applicable across types of data and
256 attempts to provide the simplest and most easily comprehensible technique that will
257 support the exchange of this broad set of data and related metadata.

258

259 The SDMX standards offer a common model and formats which support the exchange
260 of any type of statistical data meeting the definition above; an attempt has been made
261 to optimize formats based on the specific requirements of each implementation, as
262 described below in the SDMX-ML section.

263

264 The term "metadata" is very broad indeed. A distinction can be made between
265 "structural" metadata – those concepts used in the description and identification of
266 statistical data and metadata – and "reference" metadata – the larger set of concepts
267 that describe and qualify statistical data sets and processing more generally, and
268 which are often associated not with specific observations or series of data, but with
269 entire collections of data or even the institutions which provide that data.

270

271 The SDMX Information Model provides for the structuring not only of data, but also of
272 "reference" metadata. While these reference metadata structures exist independent of
273 the data and its structural metadata, they are often linked. The SDMX Information
274 Model provides for the attachment of reference metadata to any part of the data or
275 structural metadata, as well as for the reporting and exchange of the reference
276 metadata and its structural descriptions. This function of the SDMX standards is
277 intended to support many aspects of data quality initiatives, allowing as it does for the
278 exchange of metadata in its broadest sense, of which quality-related metadata is a
279 major part.

280

281 Metadata is also associated, not only with data, but also with the process of providing
282 and managing the flow of data. The SDMX Information Model provides for a set of
283 metadata concerned with "data provisioning" – metadata which is useful to those who
284 need to understand the content and form of a data provider's output. Each data
285 provider can describe in standard fashion the content of and dependencies within the
286 data- and metadata sets which they produce, and supply information about the
287 scheduling and mechanism by which their data and metadata is provided. This allows
288 for automation of some validation and control functions, as well as supporting
289 management of data reporting.

290

291 SDMX also recognizes the importance of classification schemes in organizing and
292 managing the exchange and dissemination of data and metadata. It is possible to
293 express information about classification schemes and domain categories in SDMX,
294 along with their relationships to data and metadata sets.

295

296 The formal objects in the information model are presented briefly below, but are also
297 discussed in more detail elsewhere in this specification.

298

299 ***3.4 The SDMX View of Statistical Exchange***

300

301 Version 1.0 of ISO/TS 17369 SDMX covered statistical data sets and the metadata
302 related to the structure of these data sets - "key families". This scope was useful in
303 supporting the different models of statistical exchange (bilateral exchange, gateway
304 exchange, and data-sharing) but was not by itself sufficient to support them
305 completely. Version 2.0 provides a much more complete view of statistical exchange,
306 so that an open data-sharing model can be fully supported, and other models of
307 exchange can be more completely automated. In order to produce technical standards
308 that will support this increased scope, the SDMX Information Model provides a broader
309 set of formal objects which describe the actors, processes, and resources within
310 statistical exchanges.

311
312 It is important to understand the set of formal objects not only in a technical sense,
313 however, but also in terms of what they represent in the real-world exchange of
314 statistical data and metadata.

315
316 The first version of SDMX provided for data sets - specific statistical data reported
317 according to a specific structure, for a specific time range - and for key families (data
318 structure definitions) - the metadata which describes the structure of statistical data
319 sets. These are important objects in statistical exchanges, and are retained and
320 enhanced in the second version of the standards in a backward-compatible form. A
321 related object in statistical exchanges is the "data flow" - this is the on-going
322 publication of a data set, as new observations are added to the existing ones, or as
323 subsequent data sets with the same subject and structure are published. "Data flows"
324 can be understood as data sets which are not bounded by time. Data structures are
325 owned and maintained by agencies - in a similar fashion, data flows are published by
326 "data providers", and owned by maintenance agencies.

327
328 Version 2.0 – like version 1.0 – allows for the publication of statistical data (and the
329 related structural metadata) but it also provides for the standard, systematic
330 representation of reference metadata. Reference metadata is any metadata which is
331 reported not as an integral part of a data set, but independent of the statistical data.
332 SDMX provides for reference "metadata sets", for "metadata structure definitions", and
333 also for "metadata flows". These objects are very similar to data sets, key families
334 (data structure definitions), and data flows, but they concern reference metadata rather
335 than statistical data. In the same way that data providers may publish statistical data,
336 they may also publish reference metadata. Metadata structural definitions are
337 maintained by agencies in a fashion similar to the way that agencies maintain key
338 families, the structural definitions of data sets.

339
340 The structural definitions of both data and reference metadata associate specific
341 statistical concepts with their representations, whether textual, coded, etc. In SDMX
342 version 2.0, these concepts are taken from a "concept scheme" which is maintained by
343 a specific agency. Concept schemes group a set of concepts, provide their definitions
344 and names, and allow for semantic relationships to be expressed, when some
345 concepts are specializations of others. It is possible for a single concept scheme to be
346 used both for data structures - key families - and for reference metadata structures.

347
348 Inherent in any statistical exchange – and in many dissemination activities - is a
349 concept of "service level agreement", even if this is not formalized or made explicit.
350 SDMX incorporates this idea in objects termed "provision agreements". Data providers
351 may provide data to many different data flows. Data flows may incorporate data
352 coming from more than one data provider. Provision agreements are the objects which

353 tell you which data providers are supplying what data to which data flows. The same is
354 true for metadata flows.

355

356 Provision agreements allow for a variety of information to be made available: the
357 schedule by which statistical data or metadata is reported or published, the specific
358 topics about which data or metadata is reported within the theoretically possible set of
359 data (as described by a key family or reference metadata structure definition), and the
360 time period covered by the statistical data and metadata. This set of information is
361 termed "constraints" in the SDMX Information Model. Constraints are associated with
362 data providers (typically the schedules and time periods for their data), with data flows
363 (typically describing the topics covered), and on the provision agreement (where a full
364 description of time-related constraints and topical coverage is given).

365

366 A brief summary of those objects includes:

367

368 • **Data Set:** Data is organized into discrete sets, which include particular
369 observations for a specific period of time. A data set can be understood as a
370 collection of similar data, sharing a structure, which covers a fixed period of
371 time.

372 • **Key Family (Data Structure Definition):** Each data set has a set of structural
373 metadata. These descriptions are referred to in SDMX as "key families", which
374 include information about how concepts are associated with the measures,
375 dimensions, and attributes of a data "cube," along with information about the
376 representation of data and related identifying and descriptive (structural)
377 metadata.

378 • **Codelists:** A code list is a maintained list of codes that may be used in a key
379 family or metadata structure definition. Codelists enumerate a set of values to
380 be used in the representation of dimensions, attributes, and other structural
381 parts of SDMX. They can be supplemented by metadata which indicates how
382 codes are organized into hierarchies.

383 • **Metadata Set:** A reference metadata set is a set of information regarding
384 almost any object within the formal SDMX view of statistical exchange: they
385 may describe the maintainers of data or structural definitions; they may
386 describe the schedule on which data is released; they may describe the flow of
387 a single type of data over time; they may describe the quality of data, etc. In
388 SDMX, the creators of reference metadata may take whatever concepts they
389 are concerned with, or obliged to report, and provide a reference metadata set
390 containing that information.

391 • **Metadata Structure Definition:** A reference metadata set also has a set of
392 structural metadata which describes how it is organized. This metadata
393 identifies what reference metadata concepts are being reported, how these
394 concepts relate to each other (typically as hierarchies), what their
395 presentational structure is, how they may be represented (as free text, as
396 coded values, etc.), and with which formal SDMX object types they are
397 associated.

398 • **Maintenance Agency:** In SDMX, an organization which creates and maintain
399 the structural definitions for data and metadata are called maintenance
400 agencies. Every key family and code list, for example, has an agency.

401 • **Dataflow Definition:** In SDMX, data sets are reported or disseminated
402 according to a data flow definition. The data flow definition identifies the key
403 family and may be associated with one or more subject matter domains (this
404 facilitates the search for data according to organised category schemes).

- 405 Constraints, in terms of reporting periodicity or sub set of possible keys that are
406 allowed in a data set, may be attached to the data flow definition.
- 407 • **Metadataflow Definition:** A metadata flow definition is very similar to a data
408 flow definition, but describes, categorises, and constrains metadata sets.
 - 409 • **Data Provider:** An organization which produces data or reference metadata is
410 termed a data provider.
 - 411 • **Provision Agreement:** The set of information which describes the way in
412 which data sets and metadata sets are provided by a data provider. A provision
413 agreement can be constrained in much the same way as a data or metadata
414 flow definition. Thus, a data provider can express the fact that it provides a
415 particular data flow covering a specific set of countries and topics, with a
416 particular publication schedule. Importantly, the actual source of registered data
417 or metadata is attached to the provision agreement (in terms of a URL). The
418 term “agreement” is used because this information can be understood as the
419 basis of a “service-level agreement”. In SDMX, however, this is informational
420 metadata to support the technical systems, as opposed to any sort of
421 contractual information (which is outside the scope of a technical specification).
 - 422 • **Constraints:** Constraints describe a subset of a data set or metadata set, and
423 may also provide information about scheduled releases of data. They are
424 associated with data providers, provision agreements, and data flows.
 - 425 • **Category Scheme:** Categorization schemes are made up of a hierarchy of
426 categories, which in SDMX may include any type of useful classification for the
427 organization of data and metadata.
 - 428 • **Concept Scheme:** A concept scheme is a maintained list of concepts that are
429 used in key family and metadata structure definitions. There can be many such
430 concept schemes. A “core” representation of the concept can be specified (e.g.
431 a core code list, or other representation such as “date”). Note that this core
432 representation can be overridden in the key family or metadata structure
433 definition that uses the concept. Indeed, organisations wishing to remain with
434 version 1.0 key family schema specifications will continue to declare the
435 representation in the key family definition.
 - 436 • **Structure Set:** Structure sets provide a mechanism for grouping structural
437 metadata together to form a complete description of the relationships between
438 specific, related sets of data and metadata. They can be used to map
439 dimensions and attributes to one another, to map concepts, to map codelists,
440 and to map category schemes. They can be used to describe “cubes” of data,
441 even when the data within the cube does not share a single dimensionality.
 - 442 • **Reporting Taxonomy:** A reporting taxonomy allows an organisation to link
443 (possibly in a hierarchical way) a number of cube or data flow definitions which
444 together form a complete “report” of data or metadata. This supports primary
445 reporting which often comprises multiple cubes of heterogeneous data, but may
446 also support other collection and reporting functions.
 - 447 • **Process:** The process class provides a way to model statistical processes as a
448 set of interconnected *process steps*. Although not central to the exchange and
449 dissemination of statistical data and metadata, having a shared description of
450 processing allows for the interoperable exchange and dissemination of
451 reference metadata sets which describe processes-related concepts.

452 3.4.1 Notes on Data Structuring

453

454 A “cube” is a rich, multi-dimensional construct, which can be viewed along any of its
455 axes (or “dimensions”). Whilst the full structure of cube data can be described in
456 SDMX, the actual “data” specification of SDMX takes a slightly narrower view of these
457 requirements in its version 2.0 specifications for the purposes of formatting the data for
458 transmission. The view of data in most SDMX formats is primarily as time series – that
459 is, as a set of observations which are organized around the time dimension, so that
460 each observation occurs progressively through time. This is a clear way of organizing
461 statistical data of many types, and has been proven to be a useful way of organizing
462 data for exchange between counterparties.

463

464 There are, however, some types of statistical data which are not typically organized for
465 exchange in this way – what we term “cross-sectional” data, where data are organized
466 around some other, non-time dimension of the cube. SDMX provides support for cross-
467 sectional views of data cubes. If this type of a data structure is described – and if it has
468 time as a dimension within the cube - then that data will be expressible in SDMX
469 formats which are either organized along the chosen non-time dimension, or along
470 time as a dimension. This approach gives time-series-based systems the ability to
471 process many cross-sectional data sets as well as time series.

472

473 Another type of structure commonly found in statistical “cubes” of data is the
474 hierarchical classification, used to describe the points along any of its dimensions (or
475 axes). In the 1.0 version, SDMX standards did not provide full support for this
476 functionality. The introduction of these hierarchical classifications is present in the
477 current version of the standard.

478

479 Further, there is support for the expression of functional dependencies between the
480 various dimensions of a cube, giving support for better processing of “sparse cubes”.
481 This is an aspect of “constraints”, which allow for the framing of a cube region, or for
482 the provision of a set of valid keys within the total set of keys described by the key
483 family.

484

485 **3.4.2 Notes on Reference Metadata Structuring**

486 Metadata structures are based on the idea that concepts can be organised into
487 semantic and presentational hierarchies, and that these hierarchies can form the basis
488 for the structuring of XML reporting formats. There are three message types in SDMX-
489 ML which serve this purpose: the Structure message (providing the metadata structure
490 definition), the Generic Metadata message (providing a single format for any metadata
491 structure definition), and the Metadata Report message (providing a metadata
492 structure definition-specific format). Typically, this mechanism is suited to supporting
493 reference metadata reporting and dissemination.

494

495 The Metadata Structure Definition takes *any* concept from concept schemes, and
496 describes how they can be formed into a presentational structure – either as a flat list,
497 or as a hierarchy. The concepts are assigned representations (coded, textual, etc.)
498 The “target” of the metadata – that is, the class of process, information, organisation,
499 exchange, etc. – which is the subject of the metadata is described. Because the SDMX
500 Information Model gives a formalization of statistical exchange and dissemination, the
501 model can be used as a typology of the different actors and resources within statistical
502 activities. Thus, the “targets” (subjects) of reference metadata sets and metadata flows
503 can be described as corresponding to some standard class by reference to this model.

504

505 As with data structures, there is a generic format for metadata sets and one that
506 performs a higher degree of validation, derived specifically from a metadata structure
507 definition.
508

509 **3.5 SDMX Registry Services**

510 In order to provide visibility into the large amount of data and metadata which exists
511 within the SDMX model of statistical exchange, it is felt that an architecture based on a
512 set of registry services is potentially useful. A “registry” – as understood in web-
513 services terminology – is an application which stores metadata for querying, and which
514 can be used by any other application in the network with sufficient access privileges. It
515 can be understood as the index of a distributed database or metadata repository which
516 is made up of all the data provider’s data sets and reference metadata sets within a
517 statistical community, located across the Internet or similar network.

518
519 Note that the SDMX registry services are not concerned with the storage of data or
520 reference metadata. The assumption is that data and reference metadata lives on the
521 sites of its data providers. The SDMX registry services concern themselves with
522 providing visibility of the data and reference metadata, and information needed to
523 access the data and reference metadata. Thus, a registered data set will have its URL
524 available in the registry, but not the data itself. An application which wants that data
525 would query the registry for the URL, and then have to go and retrieve the data from
526 the data provider.

527
528 SDMX does not require a particular technology implementation of the registry –
529 instead, it specifies the standard interfaces which may be supported by a registry.
530 Thus, users may implement an SDMX-conformant registry in any fashion they choose,
531 so long as the interfaces are supported as specified here. These interfaces are
532 expressed as XML documents, and form a new part of the SDMX-ML language.

533
534 The registry services discussed here can be briefly summarized:

- 535
536 • **Registration/Structural Metadata Submission:** This registry service allows
537 users with write access privileges to inform the registry that data sets,
538 reference metadata sets, structural metadata, or data provisioning information
539 exists. The registry stores a wide range of metadata about these objects.
540 Objects in the registry are organized and categorized according to one or more
541 categorization schemes.
- 542 • **Querying:** The registry services have interfaces for querying the metadata
543 contained in a registry, so that applications and users can discover the
544 existence of data sets and reference metadata sets, structural metadata, the
545 providers/agencies associated with those objects, and the provider agreements
546 which describe how the data and metadata are made available, and how they
547 are categorized.
- 548 • **Subscription/Notification:** It is possible to “subscribe” to specific objects in a
549 registry, so that a notification will be sent to all subscribers whenever the
550 registry objects are updated.
551
552

553 4 THE SDMX INFORMATION MODEL

554 SDMX provides a way of modelling statistical data, and defines the set of metadata
555 constructs used for this purpose. Because SDMX specifies formats in two syntaxes for
556 expressing data and structural metadata, the model is used as a mechanism for
557 guaranteeing that transformation between the different formats are lossless. All of the
558 formats are syntax-bound expressions of the common information model. SDMX
559 version 1.0 has based itself on GESMES/TS as an input to the model and formats,
560 both to build on the proven success of this model for time series data exchange, and to
561 ensure backward compatibility with existing GESMES/TS-based systems. Version 2.0
562 expands upon the version 1.0 basis to provide a more comprehensive model.

563
564 SDMX recognizes that statistical data is structured; in SDMX this structure is termed a
565 "key family". "Data sets" are made up of one or more lower-level "groups", based on
566 their degrees of similarity. Each group is in turn comprised of one or more "series" of
567 data (or "sections" for non-time-series data). Each series or section has a "key" -
568 values for each of a cluster of concepts, also called "dimensions" - which identifies it,
569 and one or more "observations", which typically combine the time of the observation,
570 and the value of the observation (e.g., measurement). Additionally, metadata may be
571 attached at any level of this structure as descriptive "attributes". Code lists
572 (enumerations) and other patterns for representation of data and metadata are also
573 discussed, where they are representable across syntax-specific formats.

574
575 There is some similarity between "cube" structures commonly used to process
576 statistical data, and the "key family" idea in the SDMX Information Model. It is
577 important to note that the data as structured according to the SDMX Information Model
578 is optimized for exchange, potentially with partners who have no ability to process a
579 "cube" of data coming from complex statistical systems. SDMX time series can be
580 understood as "slices" of the cube. Such a slice is identified by its key. A key consists
581 of the values for all dimensions foreseen by the key family except time. It is certainly
582 possible to reconstruct and describe data cubes from SDMX-structured data, and to
583 exchange such databases according to the proposed standards. In version 2.0, it
584 becomes possible to more fully describe the structure of cubes, with hierarchical
585 codelists, constraints, and relationships between key families.

586
587 In version 2.0, the SDMX standards also provide a view of reference metadata: a
588 mechanism for referencing the meaningful "objects" within the SDMX view of statistical
589 exchange processes (data providers, structures, provisioning agreements, dataflows,
590 metadata flows, etc.) to which metadata is attached; a mechanism for describing a set
591 of meaningful concepts, of organizing them into a presentational structure, and of
592 indicating how their values are represented. This is based on a simple, hierarchical
593 view of reference metadata which is common to many metadata systems and
594 classification/categorization schemes. SDMX provides a model (and XML formats) for
595 both describing reference metadata structures, and of reporting reference metadata
596 according to those structures.

597
598 Version 2.0 also introduces support for metadata related to the process aspects of
599 statistical exchange. A step-by-step process can be modelled; information about who
600 is providing data and reference metadata and how they are providing it can be
601 expressed; and the technical aspects of service-level agreements (and similar types of
602 provisioning agreements) can be represented.

603

604 The SDMX Information Model formally describes all of the objects listed above, so as
605 to present a standard view of the statistical exchange process.

606

607 The SDMX Information Model is presented using UML, and is also described in prose.
608 While the information model is not normative, it is a valuable tool for understanding
609 and using the normative format specifications.

610

611 **5 SDMX-EDI**

612 The SDMX-EDI format is drawn from the GESMES/TS version 3.0 implementation
613 guide, as published as a standard of the SDMX initiative.

614

615 1. *Structure Definition*: All SDMX-EDI express the data and structural metadata
616 covered by the SDMX information model in a UN/EDIFACT format.

617

618 2. *Compact Data*: Optimized for the batch exchange of large amounts of time
619 series data between counterparties, it allows for extremely compact expression
620 of large whole or partial data sets, and the structural metadata needed to
621 understand them. Non time series data, such as cross-sectional, can be
622 supported if represented as repackaged time series.

623

624 The SDMX Information Model provides the constructs which are found in the EDIFACT
625 syntax used for SDMX-EDI, and those found in the XML syntax of SDMX-ML. Since
626 both syntactic implementations reflect the same logical constructs, SDMX-EDI data
627 and metadata messages can be transformed into corresponding SDMX-ML formats,
628 and vice-versa. Thus, these standards provide for interoperability between the
629 EDIFACT- and XML-based systems processing and exchanging statistical data and
630 metadata.

631

632 **6 SDMX-ML**

633 While the SDMX-EDI format is primarily designed to support batch exchange, SDMX-
634 ML must support a wider range of requirements. XML formats are used for many
635 different types of automated processing, and thus must support more varied
636 processing scenarios. That is why there are several types of messages available as
637 SDMX-ML formats. Each is suited to support a specific set of processing requirements.

638

639 1. *Structure Definition*: All SDMX-ML message types share a common XML
640 expression of the metadata needed to understand and process a data set or
641 metadata set, and additional metadata about categorization schemes and
642 organisations is included. Also, the structural aspects of data and metadata
643 provision – dataflows and metadataflows – can be described using this format.

644

645 2. *Generic Data*: All statistical data expressible in SDMX-ML can be marked up
646 according to this data format, in agreement with the contents of a Structure
647 Definition message. It is designed for data provision on websites and in any
648 scenario where applications receiving the data may not have detailed
649 understanding of the data set's structure before they obtain the data set itself.
650 Data marked up in this format are not particularly compact, but they make
651 easily available all aspects of the data set. This format does not provide strict

- 652 validation between the data set and its structural definition using a generic XML
653 parser.
654
- 655 3. *Compact Data*: This format is specific to the key family of the data set it
656 encodes, and is created by following mappings between the metadata
657 constructs defined in the Structure Definition message and the compact format.
658 It supports the exchange of large data sets in XML format (similar to SDMX-
659 EDI), and allows for the transmission of partial data sets (incremental updates)
660 as well as whole data sets.
661
- 662 4. *Utility Data*: Many XML tools and technologies have expectations about the
663 functions performed by an XML schema, one of which is a very direct
664 relationship between the XML constructs described in the XML schema and the
665 tagged data in the XML instance. Strong datatyping is also considered normal,
666 supporting full validation of the tagged data. This message type, like the
667 Compact Data message, is specific to the key family of the data set, but is
668 designed to support validation and other expected XML schema functions. It is
669 also derived from the Structure Definition message through the implementation
670 of a set of standard mappings. It requires that a data set be complete in order
671 to validate with an XML parser.
672
- 673 5. *Cross-Sectional Data*: Unlike data oriented towards processing as time series,
674 some statistical data consists of large numbers of observations at a single point
675 in time. This message type, like the Compact Data message, is specific to the
676 key family of the data set, but is oriented for this different packaging of data.
677 The cross-sectional format is based on the same data set structure description
678 as other (time series) formats, so that searches can be made across time
679 series data, and then formatted for this type of processing if desired.
680
- 681 6. *Generic Metadata*: All reference metadata expressible in SDMX-ML format can
682 be marked up according to this schema. It performs only a minimum of
683 validation, and is somewhat verbose, but it does support the creation of generic
684 software tools and services for processing reference metadata.
685
- 686 7. *Metadata Report*: For each metadata structure definition, an XML schema
687 specific to that structure can be created, to perform validation on sets of
688 reported metadata. This structure is less verbose than the Generic Metadata
689 format, and is probably easier to use, because the XML mark-up relates directly
690 to the reported concepts. It corresponds to the Utility format for data in its
691 approach to the use of XML.
692
- 693 8. *Query*: Data and metadata are often published in databases which are
694 available on the web. Thus, it is necessary to have a standard query document
695 which allows the databases to be queried, and return an SDMX-ML message.
696 The Query document is an implementation of the SDMX Information Model for
697 use in web services and database-driven applications, allowing for a standard
698 request to be sent to data providers using these technologies.
699
- 700 9. *Registry*: All of the possible interactions with the SDMX registry services are
701 supported using SDMX-ML interfaces. These documents are almost all based
702 on a synchronous exchange of documents – a “request” message answered by
703 a “response” message. There are two basic types of request – a “Submit”,

704 which writes metadata to the registry services, and a “Query”, which is used to
705 discover that metadata. Registry interactions provide formats for all types of
706 provisioning metadata, as well as for subscription/notification, structural
707 metadata, and data and metadata registration.

708

709 Because all of the SDMX-ML formats are implementations of the same information
710 model, and all the data and metadata messages are derivable from the Structure
711 Definition message which describes a data set or metadata set, it is possible to have
712 standard mappings between each of the similar formats. These mappings can be
713 implemented in generic transformation tools, useful to all SDMX-ML users, and not
714 specific to a particular data set’s key family or metadata set’s structure definition (even
715 though some of the formats they deal with may be). Part of the SDMX-ML package is
716 the set of mappings between the key family-specific data formats and the Structure
717 Definition format from which all are derivable.

718

719 **7 CONFORMANCE**

720 This section is a normative statement of what applications must do to be considered
721 conformant with the SDMX version 2.0 specifications. This section addresses both
722 what application functionality must be supported, and the contents of an Implementor’s
723 Conformance Statement regarding SDMX conformance.

724

725 **7.1 Conformance with the SDMX Specifications**

726 SDMX standardizes the exchange of statistical data and metadata between
727 counterparties. Thus, conformance is only meaningful for applications which have an
728 exchange function between counterparties.

729 **7.2 Implementor’s Conformance Statement**

730 In order to be SDMX-conformant, an application must have an Implementor’s
731 Conformance Statement (ICS), specifying the details of conformance. The ICS states
732 which message types are supported, and how.

733

734 A “message type” is defined as an item from the following list, within groups as
735 indicated by italicized headings:

736

737 *Structure Message Types*

738 SDMX-EDI Key Family

739 SDMX-EDI Concept

740 SDMX-EDI Codelist

741 SDMX-ML Key Family

742 SDMX-ML Concept

743 SDMX-ML Codelist

744 SDMX-ML Metadata Structure Definition

745 SDMX-ML OrganisationScheme (replaces Agency)

746 SDMX-ML Hierarchical Codelist

747 SDMX-ML Structure Set

748 SDMX-ML Reporting Taxonomy

749 SDMX-ML Process

750

751

- 752 *Data Message Types*
- 753 SDMX-EDI Data
- 754 SDMX-ML Generic Data
- 755 SDMX-ML Utility Data
- 756 SDMX-ML Compact Data
- 757 SDMX-ML Cross-Sectional Data
- 758
- 759 *Metadata Message Types*
- 760 SDMX-ML Generic Metadata
- 761 SDMX-ML Metadata Report
- 762
- 763 *Query Message Types*
- 764 SDMX-ML Query
- 765
- 766 *Registry Message Types*
- 767 SDMX-ML Registry Notification
- 768 SDMX-ML Submit Subscription Request
- 769 SDMX-ML Submit Subscription Response
- 770 SDMX-ML Submit Registration Request
- 771 SDMX-ML Submit Registration Response
- 772 SDMX-ML Query Registration Request
- 773 SDMX-ML Query Registration Response
- 774 SDMX-ML Submit Structure Request
- 775 SDMX-ML Submit Structure Response
- 776 SDMX-ML Query Structure Request
- 777 SDMX-ML Query Structure Response
- 778 SDMX-ML Submit Provisioning Request
- 779 SDMX-ML Submit Provisioning Response
- 780 SDMX-ML Query Provisioning Request
- 781 SDMX-ML Query Provisioning Response

782

783 The Implementor's Conformance Statement must declare for each supported message
784 type if the application supports read functionality, write functionality, or both.

785

786 If the ICS declares support for SDMX-ML Key Families, SDMX-ML Metadata Structure
787 Definitions, SDMX-ML Codelist, SDMX-ML Concept, and/or SDMX-ML Organisation
788 Scheme, it must also state for each declaration whether structural dependencies on
789 codelists, concepts, and data providers, and agencies may be included in the message
790 by reference, inline (that is, present within the message), or both.

791

792 If the ICS declares support for the SDMX-EDI Data message type, the SDMX-ML
793 Generic Data message type, the SDMX-ML Compact Data message type, and/or the
794 SDMX-ML Cross-Sectional Data message type, then it must declare for each message
795 type whether it supports Delete actions.

796

797 If the ICS declares support for the SDMX-ML Compact Data message type, then it
798 must declare whether it supports time ranges.

799

800 **7.3 Application Functionality**

801 To be SDMX conformant, applications are required to perform specific functionality,
802 according to which message types are supported.

803

804 For each message type supported with Read functionality, a valid message must be
805 accepted as input by the application. For each message type supported with Write
806 functionality, a valid message must be produced as output by the application. For all
807 SDMX-ML message types, validity is defined in SDMX-ML:Schema and
808 Documentation, Sections V and VI. For all SDMX-EDI message types, validity is
809 defined in SDMX-EDI: Syntax and Documentation, Chapters 9 and 10.

810

811 For all applications declaring conformance for the SDMX-EDI key family structure
812 message type, the messages read or written must be valid SDMX-EDI instances,
813 containing one or more complete key families with all concepts and codelists on which
814 it has dependencies. (Codelists consist of VLI, CDV, and FTX segments; concepts of
815 STC, and FTX segments; key family definitions consist of ASI, FTX, SCD, ATT, and
816 IDE segments.)

817

818 For all applications declaring conformance for the SDMX-EDI concepts structure
819 message type, the messages read or written must be valid SDMX-EDI instances with
820 one or more STC segments containing complete concepts.

821

822 For all applications declaring conformance for the SDMX-EDI codelist structure
823 message type, the messages read or written must be valid SDMX-EDI instances with
824 at least one VLI segment containing a complete codelist.

825

826 For all applications declaring conformance for any SDMX-ML structure message types,
827 the messages read or written must be valid XML instances with a root element of
828 *StructureMessage*.

829

830 For all applications declaring conformance for SDMX-ML Key Family message types,
831 the messages read or written must be valid XML instances which include an instance
832 of the *KeyFamily* element. If support for referenced structural dependencies is
833 declared, then the application must be capable of resolving references to the key
834 family's codelists, concepts, and agencies. If support for inline structural dependencies
835 is declared, then the concepts, codelists, and agencies must be read or written from
836 within the key family's XML instance.

837

838 For all applications declaring conformance for SDMX-ML Concept message types, the
839 messages read or written must be valid XML instances which include an instance of
840 the *Concept* element.

841

842 For all applications declaring conformance for SDMX-ML Codelist message types, the
843 messages read or written must be valid XML instances which include an instance of
844 the *Codelist* element.

845

846 For all applications declaring conformance for SDMX-ML Hierarchical Codelist
847 message types, the messages read or written must be valid XML instances which
848 include an instance of the *HierarchicalCodelist* element.

849

850 For all applications declaring conformance for SDMX-ML Organisation Scheme
851 message types, the messages read or written must be valid XML instances which
852 include an instance of the *OrganisationScheme* element.

853

854 For all applications declaring conformance for SDMX-ML Metadata Structure Definition
855 message types, the messages read or written must be valid XML instances which
856 include an instance of the *MetadataStructureDefinition* element.

857

858 For all applications declaring conformance for SDMX-ML Structure Set message types,
859 the messages read or written must be valid XML instances which include an instance
860 of the *StructureSet* element.

861

862 For all applications declaring conformance for the SDMX-EDI data message type, the
863 messages read or written must be valid SDMX-EDI instances with DSI segments
864 containing the data.

865

866 For all applications declaring conformance for the SDMX-ML Generic Data message,
867 the messages read or written must be valid XML instances with a root element of
868 *GenericData* or a root element of *MessageGroup* containing one or more *GenericData*
869 elements.

870

871 For all applications declaring conformance for the SDMX-ML Utility Data message, the
872 messages read or written must be valid XML instances with a root element of
873 *UtilityData* or a root element of *MessageGroup* containing one or more *UtilityData*
874 elements, and be validatable according to an XML schema derived from a valid key
875 family according to the mappings specified.

876

877 For all applications declaring conformance for the SDMX-ML Compact Data message,
878 the messages read or written must be valid XML instances with a root element of
879 *CompactData* or a root element of *MessageGroup* containing one or more
880 *CompactData* elements, and be validatable according to an XML schema derived from
881 a valid key family according to the mappings specified.

882

883 For all applications declaring conformance for the SDMX-ML Cross-Sectional Data
884 message, the messages read or written must be valid XML instances with a root
885 element of *CrossSectionalData* or a root element of *MessageGroup* containing one or
886 more *CrossSectionalData* elements, and be validatable according to an XML schema
887 derived from a valid key family according to the mappings specified.

888

889 For all applications declaring conformance for the SDMX-ML Query message types,
890 the messages read or written must be valid XML instances with a root element of
891 *QueryMessage*.

892

893 For all applications declaring conformance for the SDMX-ML Generic Metadata
894 message, the messages read or written must be valid XML instances with a root
895 element of *GenericMetadata* or a root element of *MessageGroup* containing one or
896 more *GenericMetadata* elements.

897

898 For all applications declaring conformance for the SDMX-ML Metadata Report
899 message, the messages read or written must be valid XML instances with a root
900 element of *MetadataReport* or a root element of *MessageGroup* containing one or
901 more *MetadataReport* elements, and be validatable according to an XML schema
902 derived from a valid metadata structure definition according to the mappings specified.

903

904 For all applications declaring conformance for the SDMX-EDI data message type, and
905 support for the Delete action, it must be able to create and/or meaningfully process a

906 message where the STS segment has a status-type of “3” (data contents) and a status
907 code of “6” (delete).

908

909 For all applications declaring conformance for the SDMX-ML Generic Data message
910 type and support for the Delete action, the application must be able to create and/or
911 meaningfully process a valid *SDMXGenericDataMessage* with an *Action* code value of
912 “delete”.

913

914 For all applications declaring conformance for the SDMX-ML Compact Data message
915 type and support for the Delete action, the application must be able to create and/or
916 meaningfully process a valid *SDMXCompactDataMessage* with an *Action* code value
917 of “delete”.

918

919 For applications declaring conformance for the SDMX-ML Compact Data message
920 type and support for time ranges, the application must be able to create and/or
921 meaningfully process non-first-position observations in a series supplied without time,
922 and calculate the times for non-first position observations.

923

924 For all applications declaring conformance for the SDMX-ML Cross-Sectional Data
925 message type and support for the Delete action, the application must be able to create
926 and/or meaningfully process a valid *SDMXCrossSectionalDataMessage* with an *Action*
927 code value of “delete”.

928

929 For all applications declaring conformance for the SDMX-ML Registry Notification
930 message, the messages read or written must be valid XML instances with a
931 *RegistryNotification* element, and comply with all requirements of the SDMX Registry
932 Specification.

933

934 For all applications declaring conformance for the SDMX-ML Submit Subscription
935 Request message, the messages read or written must be valid XML instances with a
936 *SubmitSubscriptionRequest* element, and comply with all requirements of the SDMX
937 Registry Specification.

938

939 For all applications declaring conformance for the SDMX-ML Submit Subscription
940 Response message, the messages read or written must be valid XML instances with a
941 *SubmitSubscriptionResponse* element, and comply with all requirements of the SDMX
942 Registry Specification.

943

944 For all applications declaring conformance for the SDMX-ML Submit Registration
945 Request message, the messages read or written must be valid XML instances with a
946 *SubmitRegistrationRequest* element, and comply with all requirements of the SDMX
947 Registry Specification.

948

949 For all applications declaring conformance for the SDMX-ML Submit Registration
950 Response message, the messages read or written must be valid XML instances with a
951 *SubmitRegistrationResponse* element, and comply with all requirements of the SDMX
952 Registry Specification.

953

954 For all applications declaring conformance for the SDMX-ML Query Registraton
955 Request message, the messages read or written must be valid XML instances with a
956 *QueryRegistrationRequest* element, and comply with all requirements of the SDMX
957 Registry Specification.

958
959 For all applications declaring conformance for the SDMX-ML Query Registraton
960 Response message, the messages read or written must be valid XML instances with a
961 *QueryRegistrationResponse* element, and comply with all requirements of the SDMX
962 Registry Specification.
963
964 For all applications declaring conformance for the SDMX-ML Submit Structure Request
965 message, the messages read or written must be valid XML instances with a
966 *SubmitStructureRequest* element, and comply with all requirements of the SDMX
967 Registry Specification.
968
969 For all applications declaring conformance for the SDMX-ML Submit Structure
970 Response message, the messages read or written must be valid XML instances with a
971 *SubmitStructureResponse* element, and comply with all requirements of the SDMX
972 Registry Specification.
973
974 For all applications declaring conformance for the SDMX-ML Query Structure Request
975 message, the messages read or written must be valid XML instances with a
976 *QueryStructureRequest* element, and comply with all requirements of the SDMX
977 Registry Specification.
978
979 For all applications declaring conformance for the SDMX-ML Query Structure
980 Response message, the messages read or written must be valid XML instances with a
981 *QueryStructureResponse* element, and comply with all requirements of the SDMX
982 Registry Specification.
983
984 For all applications declaring conformance for the SDMX-ML Submit Provisioning
985 Request message, the messages read or written must be valid XML instances with a
986 *SubmitProvisioningRequest* element, and comply with all requirements of the SDMX
987 Registry Specification.
988
989 For all applications declaring conformance for the SDMX-ML Submit Provisioning
990 Response message, the messages read or written must be valid XML instances with a
991 *SubmitProvisioningResponse* element, and comply with all requirements of the SDMX
992 Registry Specification.
993
994 For all applications declaring conformance for the SDMX-ML Query Provisioning
995 Request message, the messages read or written must be valid XML instances with a
996 *QueryProvisioningRequest* element, and comply with all requirements of the SDMX
997 Registry Specification.
998
999 For all applications declaring conformance for the SDMX-ML Query Provisioning
1000 Response message, the messages read or written must be valid XML instances with a
1001 *QueryProvisioningResponse* element, and comply with all requirements of the SDMX
1002 Registry Specification.
1003
1004

1005 **8 DEPENDENCIES ON SDMX CONTENT STANDARDS**

1006 The technical standards proposed here are dependent on other SDMX standards
1007 which are more closely tied to the content and semantics of statistical data exchange.

1008 The SDMX Information Model works equally well with any statistical concept, but to
1009 encourage interoperability, it is also necessary to standardize and harmonize the use
1010 of specific concepts and terminology. To achieve this goal, SDMX will create and
1011 maintain guidelines for cross-domain concepts, terminology, and structural definitions.
1012 There are three major parts to this effort.
1013

1014 **8.1 Cross-Domain Metadata Concepts**

1015 The SDMX Cross-Domain Metadata Concepts is a content guideline concerning
1016 concepts which are used across many statistical domains. This list is expected to grow
1017 rapidly, and to be subject to frequent revision as SDMX is used in a growing number of
1018 domains. The use of the SDMX Cross-Domain Metadata Concepts where appropriate
1019 is not a requisite part of technical conformance, but provides a framework to promote
1020 interoperability among those who are also compliant with the technical standards
1021 presented here.
1022

1023 The harmonization of statistical concepts includes not only the definitions of the
1024 concepts, and their names, but also, where appropriate, their representations with
1025 standard codelists, and the role they play within key family structures and metadata
1026 structure definitions.
1027

1028 The intent of this guideline is two-fold: to provide a core set of concepts which can be
1029 used to structure statistical data and metadata, to promote interoperability between
1030 systems (“structural metadata”, as described above); and to promote the exchange of
1031 metadata more widely, with a set of harmonized concept names and definitions for
1032 other types of metadata (“reference metadata”, as defined above.)
1033

1034 **8.2 Metadata Common Vocabulary**

1035 The Metadata Common Vocabulary is an SDMX guideline which provides definition of
1036 terms to be used for the comparison and mapping of terminology found in key family
1037 descriptions and in other aspects of statistical metadata management. Essentially, it
1038 provides ISO/IEC 11179-compliant definitions for a wide range of statistical terms,
1039 which may be used directly, or against which other terminology systems may be
1040 mapped. This set of terms is inclusive of the terminology used within the SDMX
1041 Technical Standards.
1042

1043 The MCV provides definitions for terms on which the SDMX Cross-Domain Metadata
1044 Concepts work is built.

1045 **8.3 Statistical Subject-Matter Domains**

1046 The Statistical Subject-Matter Domains is a listing of the breadth of statistical
1047 information for the purposes of organizing widespread statistical exchange and
1048 categorization. It acts as a standard scheme against which the categorization schemes
1049 of various counterparties can be mapped, to facilitate interoperable data and metadata
1050 exchange. It serves another useful purpose, however, which is to allow an organization
1051 of corresponding “domain groups”, each of which could define standard key families,
1052 concepts, etc. within their domains. Such groups already exist within the international
1053 community. SDMX would use the Statistical Subject-Matter Domains list to facilitate
1054 the efforts of these groups to develop the kinds of content standards which could

1055 support the interoperation of SDMX-conformant technical systems within and across
1056 statistical domains.

1057

1058 SDMX Statistical Subject-Matter Domains will be listed and maintained by the SDMX
1059 Initiative and will be subject to adjustment.

1060

1061 **8.4 Non-SDMX Standards**

1062 There are also some other international standards in the metadata arena which will be
1063 of importance to the use of SDMX technical specifications moving forward. While these
1064 need not be enumerated here, there is one which promises to be very important:
1065 ISO/IEC 11179. This standard provides a structure for modelling metadata constructs
1066 which may be a powerful tool for the interoperation of metadata across systems.

1067

1068 With version 2.0 and the introduction of full support for reference metadata, SDMX is
1069 positioned to provide a mapping from its own Information Model to ISO/IEC 11179, so
1070 that other ISO/IEC 11179-compliant metadata systems can consistently use the
1071 metadata found in SDMX-compliant systems.

1072

1073 Other standards of interest include OASIS' Universal Business Language, which offers
1074 guidelines about the creation of XML schemas; and ISO/TS 15000 (ebXML), which
1075 offers a useful registry specification (parts 3 and 4) and an approach to the use of
1076 models (part 5). SDMX is actively aligned with these standards. SDMX is also looking
1077 at how it can align with several other standards.

1078

1079 **9 LOOKING FORWARD**

1080 The SDMX initiative sees this set of data and metadata formats and registry services
1081 interfaces standards as useful in creating more efficient and open systems for
1082 statistical exchange.

1083

1084 It is anticipated that SDMX will refine these standards further as they are implemented
1085 in such a way as to build on the interoperability allowed by having a set of standard
1086 formats and exchanges, based on a common information model. The review process
1087 for version 2.0 has suggested that future work could be usefully focused in the area of
1088 computational processing, especially to support a more complete approach to data
1089 quality.

1090
