## 1 Introduction

The Statistical Data and Metadata Exchange (SDMX) initiative (<https://www.sdmx.org>) sets standards that can facilitate the exchange of statistical data and metadata using modern information technology.

The SDMX Technical Specifications are organised into several discrete sections.

The following are published on the SDMX website (<https://www.sdmx.org>):

**Section 1 Framework for SDMX Technical Standards** – this document providing an introduction to the technical standards.

**Section 2 SDMX Information Model** - the SDMX information model is a standardised object model for modelling statistical domains centring on the structure of their data and metadata sets, the coding schemes used for classification, and the rules for controlling the exchange of data and metadata between organisations. This document provides a UML specification with supporting narrative.

**Section 5 SDMX Registry Specification** – an SDMX ‘registry’ acts as a repository for structural metadata and provisioning information, and a registry of data and metadata sources. This document sets out the specification.

**Section 6 SDMX Technical Notes** – detailed technical guidance for implementors of the SDMX standard.

The following are published on the GitHub repository of the SDMX Standards Technical Working Group (<https://github.com/sdmx-twg>):

### **sdmx-twg/sdmx-rest – REST API**

Technical specifications for the SDMX RESTful web services application programming interfaces (API).

### **sdmx-twg/sdmx-ml – SDMX-ML**

Technical specifications for the XML transmission format including XSD schemas, documentation and samples for data, structure and reference metadata messages.

### **sdmx-twg/sdmx-json – SDMX-JSON**

Technical specifications for the JSON transmission format including documentation, schemas and samples for data, structure and reference metadata messages.

### **sdmx-twg/sdmx-csv – SDMX-CSV**

Technical specifications for the SDMX-CSV transmission format for ‘comma-separated values’ (CSV) data and reference metadata.

The following sections are obsolete:

Section 3 - SDMX-ML - replaced by the sdmx-twg/sdmx-ml GitHub repository

Section 4 - SDMX-EDI

Section 7 - API - replaced by the sdmx-twg/sdmx-rest GitHub repository

49 VTL

50 In July 2020 the SDMX 2.1 specifications were revised to add support for the Validation and  
51 Transformation Language (VTL). For 3.0, the VTL specification has been updated to align with  
52 changes to the information model and other modifications to the Standard such as the  
53 introduction of Semantic Versioning for the versioning of structural metadata artefacts. Section  
54 2 (Information Model) sets out details of the ‘Transformation and Expressions’ package for  
55 defining and managing VTL 2.0 programs and Section 6 (Technical Notes) provides detailed  
56 guidance on implementing and using VTL with SDMX.

57

## 58 **2 Change History**

59 The 2.0 version of this standard represented a significant increase in scope, and also provided  
60 more complete support in those areas covered in the version 1.0 specification. Version 2.0 of  
61 this standard is backward-compatible with version 1.0, so that existing implementations can be  
62 easily migrated to conformance with version 2.0.

63

64 The 2.1 version of this standard represents a set of changes resulting from several years of  
65 implementation experience with the 2.0 standard. The changes do not represent a major  
66 increase in scope or functionality, but do correct some bugs, and add functionalities in some  
67 cases. Major changes in SDMX-ML include a much stronger alignment of the XML Schemas  
68 with the Information Model, to emphasize inheritance and object-oriented features, and  
69 increased precision and flexibility in the attachment of metadata reports to specific objects in the  
70 SDMX Information Model.

71

72 The 3.0 version incorporates new features, improvements and changes arising from the  
73 collective knowledge gained from a decade of operating experience with the 2.1 standard. In  
74 pursuit of modernisation and simplification, features considered obsolete have been deprecated  
75 – in particular the EDI transmission format, the lesser-used XML data messages and the SOAP  
76 web services API. Many areas remain backwardly compatible with 2.1, but there are some  
77 breaking changes where the information model has been redesigned to better support practical  
78 use case. Structure mapping and reference metadata are examples. The opportunity has been  
79 taken to revise the RESTful web services API which is also not backwardly compatible, but  
80 benefits from a rationalisation and better organisations of resources, and a much richer data  
81 query URL syntax.

82

### 83 **2.1 Major Changes from 1.0 to 2.0**

84

85 • **Reference Metadata:** In addition to describing and specifying data structures and  
86 formats (along with related structural metadata), the version 2.0 specification also  
87 provides for the exchange of metadata which is distinct from the structural metadata in  
88 the 1.0 version. This category includes “reference” metadata (regarding data quality,  
89 methodology, and similar types – it can be configured by the user to include whatever  
90 concepts require reporting); metadata related to data provisioning (release calendar  
91 information, description of the data and metadata provided, etc.); and metadata relevant  
92 to the exchange of categorization schemes.

93 • **SDMX Registry:** Provision is made in the 2.0 standard for standard communication with  
94 registry services, to support a data-sharing model of statistical exchange. These  
95 services include registration of data and metadata, querying of registered data and  
96 metadata, and subscription/notification.

- **Structural Metadata:** The support for exchange of statistical data and related structural metadata has been expanded. Some support is provided for qualitative data; data cube structures are described; hierarchical code lists are supported; relationships between data structures can be expressed, providing support for extensibility of data structures; and the description of functional dependencies within cubes are supported.

## 2.2 Major Changes from 2.0 to 2.1

- **Web-Services-Oriented Changes:** Several organizations have been implementing web services applications using SDMX, and these implementations have resulted in several changes to the specifications. Because the nature of SDMX web services could not be anticipated at the time of the original drafting of the specifications, the web services guidelines have been completely re-developed.
- **Presentational Changes:** Much work has gone into using various technologies for the visualization of SDMX data and metadata, and some changes have been proposed as a result, to better leverage this graphical visualization. These changes are largely to leverage the Cross-domain Concepts of the Content Oriented Guidelines.
- **Consistency Issues:** There have been some areas where the draft specifications were inconsistent in minor ways, and these have been addressed.
- **Clarifications in Documentation:** In some cases, it has been identified that the documentation of specific fields within the standard needed clarification and elaboration, and these issues have been addressed.
- **Optimization for XML Technologies:** Implementation has shown that it is possible to better organize the XML schemas for use within common technology development tools which work with XML. These changes are primarily focused on leveraging the object-oriented features of W3C XML Schema to allow for easier processing of SDMX data and metadata.
- **Consistency between the SDMX-ML and the SDMX Information Model:** Certain aspects of the XML schemas and UML model have been more closely aligned, to allow for easier comprehension of the SDMX model.
- **Technical Bugs:** Some minor technical bugs have been identified in the registry interfaces and elsewhere. These bugs have been addressed.
- **Support for Non-Time-Series Data in the Generic Format:** One area which has been extended is the ability to express non-time-series data as part of the generic data message.
- **Simplification of the data structure definition - specific message types:** Both time series (version 2.0 Compact) and non-time series data sets (version 2.0 Cross Sectional) use the same underlying structure for a structure-specific formatted message, which is specific to the Data Structure Definition of the data set.
- **Simplification and better support for the metadata structure:** New use cases have been reported and these are now supported by a re-modelled metadata structure definition.
- **Support for partial item schemes such as a code list:** The concept of a partial (subset) item scheme such as a partial code list for use in exchange scenarios has been introduced.

## 144 **2.3 Major Changes from 2.1 to 3.0**

145

146 SDMX version 3.0 introduces new features, improvements and changes to the Standard in the  
147 following key areas:

148

### 149 **Information Model**

- 150 • Simplification and improvement of the reference metadata model
- 151 • Support for microdata
- 152 • Support for geospatial data
- 153 • Support for code list extension and discriminated union of code lists
- 154 • Improvements to structure mapping
- 155 • Improvements to code hierarchies for data discovery
- 156 • Improvements to constraints

157

### 158 **Versioning of Structural Metadata Artefacts**

- 159 • Adoption of the three-number semantic versioning standard for structural metadata  
160 artefacts (<https://semver.org>)

161

### 162 **REST Web Services Application Programming Interface (API)**

- 163 • Change to a single 'structure' resource for structure queries simplifying the REST API  
164 specification by reducing the number of resources to five
- 165 • Improvements to data queries
- 166 • Improvements to reference metadata queries
- 167 • Support for structural metadata maintenance using HTTP PUT, POST and DELETE  
168 verbs

169

### 170 **SOAP Web Services API**

- 171 • The SOAP web services API has been deprecated with version 3.0 standardising on  
172 REST

173

### 174 **XML, JSON, CSV and EDI Transmission formats**

- 175 • The SDMX-ML, SDMX-JSON and SDMX-CSV specifications have been extended and  
176 modified where needed to support the new features and changes such as reference  
177 metadata and microdata
- 178 • The SDMX-EDI transmission format for structures and data has been deprecated
- 179 • Obsolete SDMX-ML data messages including Generic, Generic Time Series and  
180 Structure Specific Time Series have been deprecated standardising on Structure  
181 Specific Data as the sole XML format for data exchange

182

183 SDMX 3.0 messages may continue to be converted between transmission formats without loss  
184 of information.

185

186 Several of the changes are 'breaking' meaning that, in specific cases, the version 3.0  
187 specification is not backwardly compatible with earlier versions of the Standard.

188 The SDMX 3.0 Major Changes document provides more information including an analysis of  
189 the breaking changes.

## 190 3 Processes and Business Scope

### 191 3.1 Process Patterns

192 SDMX identifies three basic process patterns regarding the exchange of statistical data and  
193 metadata. These can be described as follows:

194

195 1. *Bilateral exchange*: All aspects of the exchange process are agreed between  
196 counterparties, including the mechanism for exchange of data and metadata, the  
197 formats, the frequency or schedule, and the mode used for communications regarding  
198 the exchange. This is perhaps the most common process pattern.

199

200 2. *Gateway exchange*: Gateway exchanges are an organized set of bilateral exchanges,  
201 in which several data and metadata collecting organizations or individuals agree to  
202 exchange the collected information with each other in a single, known format, and  
203 according to a single, known process. This pattern has the effect of reducing the  
204 burden of managing multiple bilateral exchanges (in data and metadata collection)  
205 across the sharing organizations/individuals. This is also a very common process  
206 pattern in the statistical area, where communities of institutions agree on ways to gain  
207 efficiencies within the scope of their collective responsibilities.

208

209 3. *Data-sharing exchange*: Open, freely available data formats and process patterns are  
210 known and standard. Thus, any organization or individual can use any counterparty's  
211 data and metadata (assuming they are permitted access to it). This model requires  
212 no bilateral agreement, but only requires that data and metadata providers and  
213 consumers adhere to the standards.

214

215 This document specifies the SDMX standards designed to facilitate exchanges based on any  
216 of these process patterns, and shows how SDMX offers advantages in all cases. It is possible  
217 to agree bilaterally to use a standard format (such as SDMX-ML or SDMX-JSON); it is  
218 possible for data senders in a gateway process to use a standard format for data exchange  
219 with each other, or with any data providers who agree to do so; it is possible to agree to use  
220 the full set of SDMX standards to support a common data-sharing process of exchange,  
221 whether based on an SDMX-conformant registry or some other architecture.

222

223 The standards specified here specifically support a data-sharing process based on the use  
224 of central registry services. Registry services provide visibility into the data and metadata  
225 existing within the community, and support the access and use of this data and metadata by  
226 providing a set of triggers for automated processing. The data or metadata itself is not stored  
227 in a central registry – these services merely provide a useful set of metadata about the data  
228 (and additional metadata) in a known location, so that users/applications can easily locate  
229 and obtain whatever data and/or metadata is registered. The use of standards for all data,  
230 metadata, and the registry services themselves is ubiquitous, permitting a high level of  
231 automation within a data-sharing community.

232

233 It should be pointed out that these different process models are not mutually exclusive – a  
234 single system capable of expressing data and metadata in SDMX-conformant formats could  
235 support all three scenarios. Different standards may be applicable to different processes (for

236 example, many registry services interfaces are used only in a data-sharing scenario) but all  
237 have a common basis in a shared information model.

238

239 In addition to looking at collection and reporting, it is also important to consider the  
240 dissemination of data. Data and metadata – no matter how they are exchanged between  
241 counterparties in the process of their development and creation – are all eventually supplied  
242 to an end user of some type. Often, this is through specific applications inside of institutions.  
243 But more and more frequently, data and metadata are also published on websites in various  
244 formats. The dissemination of data and its accompanying metadata on the web is a focus of  
245 the SDMX standards. Standards for statistical data and metadata allow improvements in the  
246 publication of data – it becomes more easily possible to process a standard format once the  
247 data is obtained, and the data and metadata are linked together, making the comprehension  
248 and further processing of the data easier.

249

250 In discussions of statistical data, there are many aspects of its dissemination which impact  
251 data quality: data discovery, ease of use, and timeliness. SDMX standards provide support  
252 for all of these aspects of data dissemination. Standard data formats promote ease of use,  
253 and provide links to relevant metadata. The concept of registry services means that data and  
254 metadata can more easily be discovered. Timeliness is improved throughout the data  
255 lifecycle by increases in efficiency, promoted through the availability of metadata and ease  
256 of use.

257

258 It is important to note that SDMX is primarily focused on the *exchange* and *dissemination* of  
259 statistical data and metadata. There may also be many uses for the standard model and  
260 formats specified here in the context of internal processing of data that are not concerned  
261 with the exchange between organizations and users, however. It is felt that a clear, standard  
262 formatting of data and metadata for the purposes of exchange and dissemination can also  
263 facilitate internal processing by organizations and users, but this is not the focus of the  
264 specification.

### 265 **3.2 SDMX and Process Automation**

266 Statistical data and metadata exchanges employ many different automated processes, but  
267 some are of more general interest than others. There are some common information  
268 technologies that are nearly ubiquitous within information systems today. SDMX aims to  
269 provide standards that are most useful for these automated processes and technologies.

270

271 Briefly, these can be described as:

272

273 1. *Batch Exchange of Data and Metadata:* The transmission of whole or partial  
274 databases between counterparties, including incremental updating.

275

276 2. *Provision of Data and Metadata on the Internet:* Internet technology - including its use  
277 in private or semi-private TCP/IP networks - is extremely common. This technology  
278 includes XML, JSON and REST web services as primary mechanisms for automating  
279 data and metadata provision, as well as the more traditional static HTML and  
280 database-driven publishing.

281

282 3. *Generic Processes:* While many applications and processes are specific to some set  
283 of data and metadata, other types of automated services and processes are designed

284 to handle any type of statistical data and metadata whatsoever. This is particularly  
285 true in cases where portal sites and data feeds are made available on the Internet.

286

287 4. *Presentation and Transformation of Data*: In order to make data and metadata useful  
288 to consumers, they must support automated processes that transform them into  
289 application-specific processing formats, other standard formats, and presentational  
290 formats. Although not strictly an aspect of exchange, this type of automated  
291 processing represents a set of requirements that must be supported if the information  
292 exchange between counterparties is itself to be supported.

293

294 The SDMX standards specified here are designed to support the requirements of all of these  
295 automation processes and technologies.

### 296 **3.3 Statistical Data and Metadata**

297 To avoid confusion about which "data" and "metadata" are the intended content of the SDMX  
298 formats specified here, a statement of scope is offered. Statistical "data" are sets of often  
299 numeric observations which typically have time associated with them. They are associated  
300 with a set of metadata values, representing specific concepts, which act as identifiers and  
301 descriptors of the data. These metadata values and concepts can be understood as the  
302 named dimensions of a multi-dimensional co-ordinate system, describing what is often called  
303 a "cube" of data.

304

305 SDMX identifies a standard technique for modelling, expressing, and understanding the  
306 structure of this multi-dimensional "cube", allowing automated processing of data from a  
307 variety of sources. This approach is widely applicable across types of data and attempts to  
308 provide the simplest and most easily comprehensible technique that will support the  
309 exchange of this broad set of data and related metadata.

310

311 The term "metadata" is very broad indeed. A distinction can be made between "structural"  
312 metadata – those concepts used in the description and identification of statistical data and  
313 metadata – and "reference" metadata – the larger set of concepts that describe and qualify  
314 statistical data sets and processing more generally, and which are often associated not with  
315 specific observations or series of data, but with entire collections of data or even the  
316 institutions which provide that data.

317

318 The SDMX Information Model provides for the structuring not only of data, but also of  
319 "reference" metadata. While these reference metadata structures exist independent of the  
320 data and its structural metadata, they are often linked. The SDMX Information Model provides  
321 for the attachment of reference metadata to any part of the data or structural metadata, as  
322 well as for the reporting and exchange of the reference metadata and its structural  
323 descriptions. This function of the SDMX standards supports many aspects of data quality  
324 initiatives, allowing as it does for the exchange of metadata in its broadest sense, of which  
325 quality-related metadata is a major part.

326

327 Metadata are associated not only with data, but also with the process of providing and  
328 managing the flow of data. The SDMX Information Model provides for a set of metadata  
329 concerned with "data provisioning" – metadata which are useful to those who need to  
330 understand the content and form of a data provider's output. Each data provider can describe  
331 in standard fashion the content of and dependencies within the data and metadata sets which

332 they produce, and supply information about the scheduling and mechanism by which their  
333 data and metadata are provided. This allows for automation of some validation and control  
334 functions, as well as supporting management of data reporting.

335

336 SDMX also recognizes the importance of classification schemes in organizing and managing  
337 the exchange and dissemination of data and metadata. It is possible to express information  
338 about classification schemes and domain categories in SDMX, along with their relationships  
339 to data and metadata sets, as well as to categorize other objects in the model.

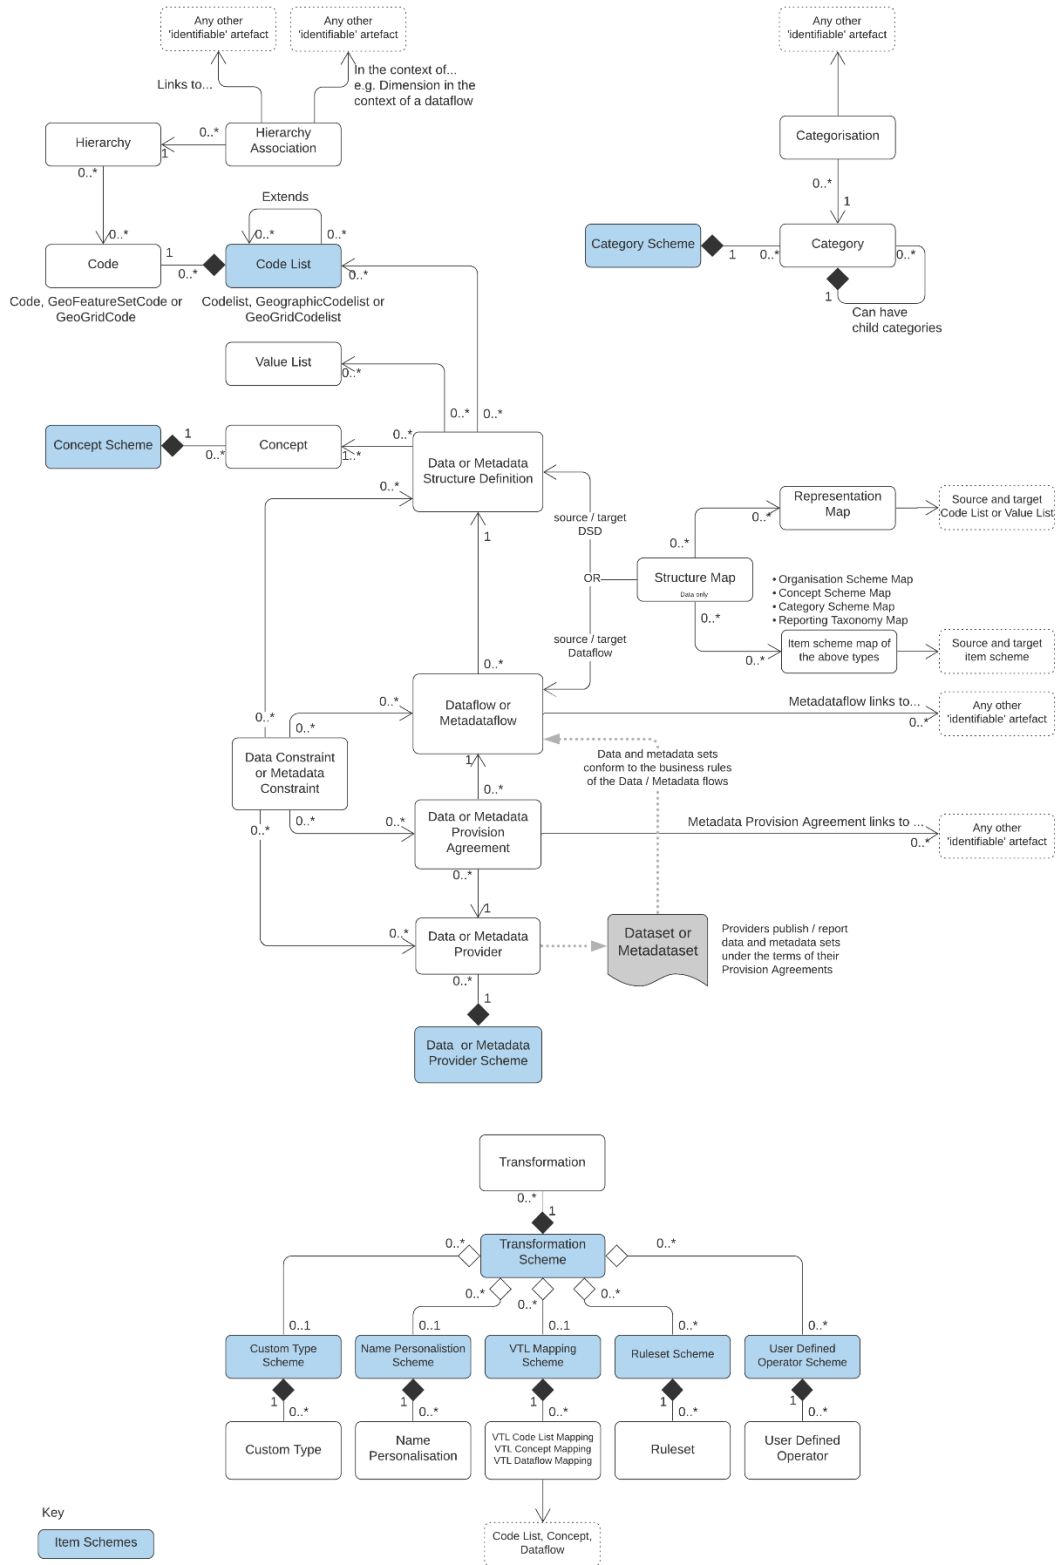

340

341 The SDMX standards offer a common model, a choice of syntax and, for XML, a choice of  
342 data formats which support the exchange of any type of statistical data meeting the definition  
343 above; several optimized formats are specified based on the specific requirements of each  
344 implementation, as described below in the SDMX-ML section.

345

346 The formal objects in the information model are presented schematically in Figure 1, and are  
347 discussed in more detail elsewhere in this document.

348

349  
350

Figure 1: High Level Schematic of Major Artefacts in the SDMX 3.0 Information Model

### 351 **3.4 The SDMX View of Statistical Exchange**

352 Version 1.0 of ISO/TS 17369 SDMX covered statistical data sets and the metadata related  
353 to the structure of these data sets. This scope was useful in supporting the different models  
354 of statistical exchange (bilateral exchange, gateway exchange, and data-sharing) but was  
355 not by itself sufficient to support them completely. Versions 2.0 and 2.1 provide a much more  
356 complete view of statistical exchange, so that an open data-sharing model can be fully  
357 supported, and other models of exchange can be more completely automated. In order to  
358 produce technical standards that will support this increased scope, the SDMX Information  
359 Model provides a broader set of formal objects which describe the actors, processes, and  
360 resources within statistical exchanges.

361  
362 It is important to understand the set of formal objects not only in a technical sense, but also  
363 in terms of what they represent in the real-world exchange of statistical data and metadata.  
364

365 The first version of SDMX provided for data sets - specific statistical data reported according  
366 to a specific structure, for a specific time range - and for data structure definitions - the  
367 metadata which describes the structure of statistical data sets. These are important objects  
368 in statistical exchanges, and are retained and enhanced in the second version of the  
369 standards in a backward-compatible form. A related object in statistical exchanges is the  
370 "data flow" - this supports the concept of data reporting or dissemination on an ongoing basis.  
371 "Data flows" can be understood as data sets which are not bounded by time. Data structures  
372 are owned and maintained by agencies - in a similar fashion, data flows are owned by  
373 maintenance agencies.  
374

375 SDMX allows for the publication of statistical data (and the related structural metadata) but  
376 also provided for the standard, systematic representation of reference metadata. In version  
377 2.1, reference metadata were reported independent of the statistical data. However, in 3.0  
378 reference metadata associated directly with data such as footnotes are reported as attributes  
379 of the data set. For other reference metadata, principally that linked to structures like  
380 "concepts", SDMX provides reference "metadata sets", "metadata structure definitions", and  
381 "metadata flows". These objects are very similar to data sets, data structure definitions, and  
382 data flows, but concern reference metadata rather than statistical observations. In the same  
383 way that data providers may publish statistical data, they may also publish reference  
384 metadata. Metadata structural definitions are maintained by agencies in a fashion similar to  
385 the way that agencies maintain data structure definitions, the structural definitions of data  
386 sets.  
387

388 The structural definitions of both data and reference metadata associate specific statistical  
389 concepts with their representations, whether textual, coded, etc. These concepts are taken  
390 from a "concept scheme" which is maintained by a specific agency. Concept schemes group  
391 a set of concepts, provide their definitions and names, and allow for semantic relationships  
392 to be expressed, when some concepts are specializations of others. It is possible for a single  
393 concept scheme to be used both for data structures - key families - and for reference  
394 metadata structures.  
395

396 Inherent in any statistical exchange – and in many dissemination activities – is a concept of  
397 "service level agreement", even if this is not formalized or made explicit. SDMX incorporates  
398 this idea in objects termed "provision agreements". Data providers may provide data to many  
399 different data flows. Data flows may incorporate data coming from more than one data

400 provider. Provision agreements are the objects which tell you which data providers are  
401 supplying what data to which data flows. Similarly, metadata provision agreements for  
402 metadata flows.

403

404 Provision agreements allow for a variety of information to be made available: the schedule  
405 by which statistical data or metadata is reported or published, the specific topics about which  
406 data or metadata is reported within the theoretically possible set of data (as described by a  
407 data structure definition or reference metadata structure definition), and the time period  
408 covered by the statistical data and metadata. This set of information is termed "constraint" in  
409 the SDMX Information Model.

410

411 A brief summary of the objects described in the information model includes:

412

413 • **Data Set:** Data is organized into discrete sets, which include particular observations  
414 for a specific period of time. A data set can be understood as a collection of similar  
415 data, sharing a structure, which covers a fixed period of time.

416 • **Data Structure Definition (DSD, also known as Key Family in Version 2.0):** Each  
417 data set has a set of structural metadata. These descriptions are referred to in SDMX  
418 as Data Structure Definitions, which include information about how concepts are  
419 associated with the measures, dimensions, and attributes of a data "cube," along with  
420 information about the representation of data and related identifying and descriptive  
421 (structural) metadata. In Version 2.1, the term "Key Family" was replaced by "Data  
422 Structure Definition" (DSD) both in XML Schemas and the Information Model. The  
423 DSD has been modified in version 3.0 to better support microdata by providing the  
424 option to define multiple measures and for attributes and measures to take arrays of  
425 values.

426 • **Code list:** Code lists enumerate a set of codes to be used in the representation of  
427 dimensions, attributes, and other structural parts of SDMX. Codes can be organised  
428 into simple hierarchies within a code list, and more complex hierarchies potentially  
429 involving multiple code lists using hierarchy and hierarchy association structures.

430 • **Value list:** Value lists introduced in version 3.0 are similar to codelists with the  
431 exception that the items do not need to conform to the usual SDMX rules for  
432 identifiable objects. That allows the values to include characters such as currency  
433 symbols (e.g. ¥) which would otherwise make illegal codes. However, unlike codes,  
434 values are not individually identifiable. Value lists find application in concepts and  
435 data structures definitions for less structured data and microdata enumerations and  
436 can be mapped to other value or code lists using representation maps.

437 • **Organisation Scheme:** Organisations and organisation structure can be defined in  
438 an Organisation Scheme. Specific Organisation Schemes exist for Maintenance  
439 Agency, Data Provider, Metadata Provider, Data Consumer, and Organisation Unit.

440 • **Category Scheme and Categorisation:** Category schemes are made up of a  
441 hierarchy of categories, which in SDMX may include any type of useful classification  
442 for the organization of data and metadata. A Categorisation links a category to an  
443 identifiable object. In this way sets of objects can be categorised. A statistical subject-  
444 matter domain scheme is implemented in SDMX as a Category Scheme.

445 • **Concept Scheme:** A concept scheme is a maintained list of concepts that are used  
446 in data structure definitions and metadata structure definitions. There can be many  
447 such concept schemes. A "core" representation of the concept can be specified (e.g.  
448 a core code list, or other representation such as "date"). Note that this core

- 449 representation can be overridden in the data structure definition or metadata structure  
450 definition that uses the concept. Indeed, organisations wishing to remain with version  
451 1.0 key family schema specifications will continue to declare the representation in the  
452 key family definition.
- 453 • **Metadata Set:** A reference metadata set is a set of information pertaining to an object  
454 within the formal SDMX view of statistical exchange: they may describe the  
455 maintainers of data or structural definitions; they may describe the schedule on which  
456 data is released; they may describe the flow of a single type of data over time; they  
457 may describe the quality of data, etc. In SDMX, the creators of reference metadata  
458 may take whatever concepts they are concerned with, or obliged to report, and  
459 provide a reference metadata set containing that information.
  - 460 • **Metadata Structure Definition:** A reference metadata set also has a set of structural  
461 metadata which describes how it is organized. This metadata set identifies what  
462 reference metadata concepts are being reported, how these concepts relate to each  
463 other (typically as hierarchies), what their presentational structure is, how they may  
464 be represented (as free text, as coded values, etc.), and with which formal SDMX  
465 object types they are associated.
  - 466 • **Dataflow Definition:** In SDMX, data sets are reported or disseminated according to  
467 a data flow definition. The data flow definition identifies the data structure definition  
468 and may be associated with one or more subject matter domains via a Categorisation  
469 (this facilitates the search for data according to organised category schemes).  
470 Constraints, in terms of reporting periodicity or sub set of possible keys that are  
471 allowed in a data set, may be attached to the data flow definition.
  - 472 • **Metadataflow Definition:** A metadata flow definition is very similar to a data flow  
473 definition, but describes, categorises, and constrains metadata sets.
  - 474 • **Data Provider:** An organization which produces data is termed a data provider.
  - 475 • **Metadata Provider:** An organization which produces reference metadata is termed  
476 a metadata provider.
  - 477 • **Provision Agreement (Metadata Provision Agreement):** The set of information  
478 which describes the way in which data sets and metadata sets are provided by a  
479 data/metadata provider. A provision agreement can be constrained in much the same  
480 way as a data or metadata flow definition. Thus, a data provider can express the fact  
481 that it provides a particular data flow covering a specific set of countries and topics,  
482 Importantly, the actual source of registered data or metadata is attached to the  
483 provision agreement (in terms of a URL). The term “agreement” is used because this  
484 information can be understood as the basis of a “service-level agreement”. In SDMX,  
485 however, this is informational metadata to support the technical systems, as opposed  
486 to any sort of contractual information (which is outside the scope of a technical  
487 specification). In version 3.0, metadata provision agreement and data provision  
488 agreement are two separate artefacts.
  - 489 • **Constraint:** Data and Metadata Constraints describe a subset of a data source or  
490 metadata source, and may also provide information about scheduled releases of data.  
491 They are associated with data / metadata providers, provision agreements, data  
492 flows, metadataflows, data structure definitions and metadata structure definitions.
  - 493 • **Structure Map:** Structure maps describes a mapping between data structure  
494 definitions or dataflows for the purpose of transforming a data set into a different  
495 structure. The mapping rules are defined using one or more component maps which  
496 each map in turn describes how one or more components from the source data  
497 structure definition map to one or more components in that of the target. Represent

- 498 maps act as lookup tables and specific provision is made for mapping dates and  
499 times.
- 500 • **Representation Map:** Representation maps describe mappings between source  
501 value(s) and target value(s) where the values are restricted to those in a code list,  
502 value list or be of a certain type such as integer or string.
  - 503 • **Item Scheme Map:** An item scheme map describes mapping rules between any item  
504 scheme with the exception of code lists and value lists which use representation  
505 maps. The version 3.0 information model provides four item scheme maps:  
506 organisation scheme map, concept scheme map, category scheme map and  
507 reporting taxonomy map.
  - 508 • **Reporting Taxonomy:** A reporting taxonomy allows an organisation to link (possibly  
509 in a hierarchical way) a number of cube or data flow definitions which together form a  
510 complete “report” of data or metadata. This supports primary reporting which often  
511 comprises multiple cubes of heterogeneous data, but may also support other  
512 collection and reporting functions. It also supports the specification of publications  
513 such as a yearbook, in terms of the data or metadata contained in the publication.
  - 514 • **Process:** The process class provides a way to model statistical processes as a set  
515 of interconnected *process steps*. Although not central to the exchange and  
516 dissemination of statistical data and metadata, having a shared description of  
517 processing allows for the interoperable exchange and dissemination of reference  
518 metadata sets which describe processes-related concepts.
  - 519 • **Hierarchy:** Describes complex code hierarchies principally for data discovery  
520 purposes. The codes themselves are referenced from the code lists in which they are  
521 maintained.
  - 522 • **Hierarchy Association:** A hierarchy association links a hierarchy to something that  
523 needs it like a dimension. Furthermore, the linking can be specified in the context of  
524 another object such as a dimension in the context of a dataflow. Thus, a dimension  
525 in a data structure definition could have different hierarchies depending on the  
526 dataflow.
  - 527 • **Transformation Scheme:** A transformation scheme is a set of Validation and  
528 Transformation Language (VTL) transformations aimed at obtaining some meaningful  
529 results for the user (e.g., the validation of one or more data sets). The set of  
530 transformations is meant to be executed together (in the same run) and may contain  
531 any number of transformations in order to produce any number of results. Thus, a  
532 transformation scheme can be considered as a VTL ‘program’.
  - 533
  - 534

### 535 **3.5 SDMX Registry Services**

536 In order to provide visibility into the large amount of data and metadata which exists within  
537 the SDMX model of statistical exchange, it is felt that an architecture based on a set of registry  
538 services is potentially useful. A “registry” – as understood in webservices terminology – is an  
539 application which maintains and stores metadata for querying, and which can be used by any  
540 other application in the network with sufficient access privileges (though note that the  
541 mechanism of access control is outside of the scope of the SDMX standard). It can be  
542 understood as the index of a distributed database or metadata repository which is made up  
543 of all the data provider’s data sets and reference metadata sets within a statistical community,  
544 located across the Internet or similar network.

545  
546 Note that the SDMX registry services are not concerned with the storage of data or reference  
547 metadata. The assumption is that data and reference metadata lives on the sites of its data  
548 and metadata providers. The SDMX registry services concern themselves with providing  
549 visibility of the data and reference metadata, and information needed to access the data and  
550 reference metadata. Thus, a registered data set will have its URL available in the registry,  
551 but not the data itself. An application which wishes to access that data would query the  
552 registry, perhaps by drilling down via a Category Scheme and Dataflow, for the URL of a  
553 registered data source, and then retrieve the data directly from the data provider (using an  
554 SDMX REST API query message or other mechanism).

555  
556 SDMX does not require a particular technology implementation of the registry – instead, it  
557 specifies the standard interfaces which may be supported by a registry. Thus, users may  
558 implement an SDMX-conformant registry in any fashion they choose, provided the interfaces  
559 are supported as specified in Section 5 on the Registry Specification. These interfaces are  
560 expressed as XML documents, but also REST API request/response messages

561  
562 The registry services discussed here can be briefly summarized:

- 563  
564 • **Maintenance of Structural Metadata:** This registry service allows users with  
565 maintenance agency access privileges to submit and modify structural metadata. In  
566 this aspect the registry is acting as a structural metadata repository. However, it is  
567 permissible in an SDMX structure to submit just the “stub” of the structural object,  
568 such as a code list, and for this stub to reference the actual location from where the  
569 metadata can be retrieved, either from a file or a structural metadata resource, such  
570 as another registry.
- 571 • **Registration of Data and Metadata Sources:** This registry service allows users with  
572 maintenance agency access privileges to inform the registry of the existence and  
573 location (for retrieval) of data sets and reference metadata sets. The registry stores  
574 metadata about these objects, and links it to the structural metadata that give  
575 sufficient structural information for an application to process it, or for an application to  
576 discover its existence. Objects in the registry are organized and categorized  
577 according to one or more category schemes.
- 578 • **Querying:** The registry services have interfaces for querying the metadata contained  
579 in a registry, so that applications and users can discover the existence of data sets  
580 and reference metadata sets, structural metadata, the providers/agencies associated  
581 with those objects, and the provider agreements which describe how the data and  
582 metadata are made available, and how they are categorized.

- 583       • **Subscription/Notification:** It is possible to “subscribe” to specific objects in a  
584 registry, so that a notification will be sent to all subscribers whenever the registry  
585 objects are updated.

### 586 **3.6 RESTful Web services**

587 Web services allow computer applications to exchange data directly over the Internet,  
588 essentially allowing modular or distributed computing in a more flexible fashion than ever  
589 before. In order to allow web services to function, however, many standards are required:  
590 for requesting and supplying data; for expressing the enveloping data which is used to  
591 package exchanged data; for describing web services to one another, to allow for easy  
592 integration into applications that use other web services as data resources.

593 Version 3.0 has standardized on RESTful web services with a OpenAPI specification  
594 published on the SDMX Technical Working Group’s GitHub repository  
595 <https://github.com/sdmx-twg>. There are five ‘resources’:

- 596       • structure – retrieval and maintenance of structural metadata
- 597       • data – retrieval of data
- 598       • schema – retrieval of XML schemas to validate specific data or metadata sets
- 599       • availability – retrieval of information on the data available for a Dataflow
- 600       • metadata – retrieval of reference metadata

601 The following conceptual example uses the ‘data’ resource to query a data repository for a  
602 series identified by the key ‘M.USD.EUR.SP00.A’ in the EXR (ECB exchange rates)  
603 Dataflow:

604       <https://ws-entry-point/data/dataflow/ECB/EXR/1.0.0/M.USD.EUR.SP00.A>  
605

## 606 **4 The SDMX Information Model**

607 SDMX provides a way of modelling statistical data, and defines the set of metadata constructs  
608 used for this purpose. Because SDMX specifies a number of transmission formats for  
609 expressing data and structural metadata, the model is used as a mechanism for guaranteeing  
610 that transformation between the different formats is lossless. In this sense, all of the formats  
611 are syntax-bound expressions of the common information model.

612  
613 SDMX recognizes that statistical data is structured; in SDMX this structure is termed a Data  
614 Structure Definition. “Data sets” are made up of one or more lower-level “groups”, based on  
615 their degrees of similarity. Each group is in turn comprised of one or more “series” of data.  
616 Each series or section has a “key” - values for each of a cluster of concepts, also called  
617 “dimensions” - which identifies it, and one or more “observations”, which typically combine  
618 the time of the observation, and the value of the observation (e.g., measurement).  
619 Additionally, metadata may be attached at any level of this structure as descriptive  
620 “attributes”. Code lists (enumerations) and other patterns for representation of data and  
621 metadata are also modelled.  
622

623 There is some similarity between “cube” structures commonly used to process statistical data,  
624 and the Data Structure Definition idea in the SDMX Information Model. It is important to note  
625 that the data as structured according to the SDMX Information Model is optimized for  
626 exchange, potentially with partners who may have no ability to process a “cube” of data  
627 coming from complex statistical systems. SDMX time series can be understood as “slices” of  
628 the cube. Such a slice is identified by its key. A "series" key consists of the values for all  
629 dimensions specified by the key family except time. Thus, it is possible to reconstruct and  
630 describe data cubes from SDMX-structured data, and to exchange such databases using the  
631 interfaces and formats provided for that purpose in the standard. Additional objects such as  
632 hierarchical code lists, constraints and structure maps make it possible to more fully model  
633 the structure of cubes.

634  
635 The information model also provides a view of reference metadata: a mechanism for  
636 referencing the meaningful “objects” within the SDMX view of statistical exchange processes  
637 (data providers, structures, provisioning agreements, dataflows, metadata flows, etc.) to  
638 which metadata is attached; a mechanism for describing a set of meaningful concepts, of  
639 organizing them into a presentational structure, and of indicating how their values are  
640 represented. This is based on a simple, hierarchical view of reference metadata which is  
641 common to many metadata systems and classification/categorization schemes. SDMX  
642 provides a model (and XML and JSON formats) for both describing reference metadata  
643 structures, and of reporting reference metadata according to those structures.

644  
645 Version 2.0/2.1 introduced support for metadata related to the process aspects of statistical  
646 exchange. A step-by-step process can be modelled; information about who is providing data  
647 and reference metadata and how they are providing it can be expressed; and the technical  
648 aspects of service-level agreements (and similar types of provisioning agreements) can be  
649 represented.

650  
651 Support for the Validation and Transformation Language (VTL) in the SDMX Information  
652 Model was introduced in the July 2020 revision of 2.1 and is retained in version 3.0 with  
653 minimal changes. This allows reusable VTL ‘programs’ (a cohesive set of transformation  
654 statements designed to be executed together) and their associated constructs such as  
655 validation rulesets and user-defined operators to be managed and exchanged as SDMX  
656 structural metadata. Mappings between objects such as data sets referenced in VTL  
657 programs and the actual SDMX artefacts to which they relate is essential when it comes to  
658 actually executing programs, and this information can also be defined. Chapter 7 has more  
659 information on VTL and its integration with SDMX.

660  
661 A full UML conceptual design of the information model is set out in Section 2 of the Technical  
662 Specifications.

## 663 **5 The SDMX Transmission Formats**

### 664 **5.1 SDMX-ML**

665 SDMX-ML is the XML transmission format specification for exchanging structural metadata,  
666 data and reference metadata, and interacting with SDMX registry services. It is designed as  
667 a general-purpose format for all automation and data / metadata exchange tasks, and  
668 provides the most complete coverage.

669

670 There are four distinct types of message:

671

672 1. *Structure Definition*: For the exchange of structural metadata. A SDMX-ML structure  
673 message can carry details of any number and combination of structural metadata  
674 artefacts like DSDs, code lists and constraints.

675

676 2. *Structure-specific Data*: For the exchange of data. This format is specific to the Data  
677 Structure Definitions of the data sets (in other terms, it is DSD-specific) and is created  
678 by following mappings between the metadata constructs defined in the Structure  
679 Definition message and the technical specification of the format. It supports the  
680 exchange of large data sets in XML format, provides strict validation of conformance  
681 with the DSD using a generic XML parser, and supports the transmission of partial  
682 data sets (incremental updates) as well as whole data sets.

683

684 Many XML tools and technologies have expectations about the functions performed  
685 by an XML schema, one of which is a very direct relationship between the XML  
686 constructs described in the XML schema and the tagged data in the XML instance.  
687 Strong data typing is also considered normal, supporting full validation of the tagged  
688 data. These message types are designed to support validation and other expected  
689 XML schema functions.

690

691 3. *Generic Metadata*: For the exchange of reference metadata sets. ‘Generic’ means  
692 the XML elements and XML attributes are the same regardless of the metadata set.

693

694 4. *Registry*: All of the possible interactions with the SDMX registry services are  
695 supported using SDMX-ML interfaces and REST API calls. Submission of structural  
696 metadata content, data / metadata registrations and subscriptions is performed by a  
697 synchronous exchange of documents – a “request” message answered by a  
698 “response” message.

699

## 700 **5.2 SDMX-JSON**

701 SDMX-JSON is the JSON transmission format specification for exchanging structural  
702 metadata, data and reference metadata. It provides an alternative to SDMX-ML and is most  
703 suited to applications like web data dissemination.

704

705 SDMX-JSON messages serve the same function as those of the XML formats but have a  
706 different structure. For data, an important distinction is that they carry both component codes  
707 and labels which provides all the information needed to display the content in a single JSON  
708 response. The XML Structure-specific Data format by contrast carries only code IDs thus  
709 requiring applications obtain and hold structural metadata about the data set in order to display  
710 the content in human-readable form.

711

712 SDMX-JSON does not include messages for subscription / notification or registration registry  
713 services - SDMX-ML must be used for those purposes.

714

715 There are three distinct message types:

716 1. *Structure*: For the exchange structural metadata. SDMX-JSON structure messages  
717 follow the same principles as for SDMX-ML in that a single message can transmit any

718 number and combination of structural metadata artefacts. While the SDMX-ML and  
719 SDMX-JSON messages are structured differently, it is possible to freely convert  
720 between them.

721

722 2. *Data*: For the exchange of data. Unlike SDMX-ML, the structure of a SDMX-JSON  
723 data message is not specific to the DSDs of the data sets so schema validation will  
724 not check for compliance of the data with the DSDs.

725

726 3. *Metadata*: For the exchange of reference metadata sets.

727

### 728 **5.3 SDMX-CSV**

729 SDMX-CSV is the CSV transmission format specification for exchanging data and reference  
730 metadata only.

731

732 SDMX-CSV provides a simple columnar format for data and metadata that can be readily  
733 created and interpreted by standard software tools such as Microsoft Excel. Nevertheless, data  
734 and metadata can still be converted between the CSV and the JSON / XML formats without  
735 loss.

736

737 There are two distinct message types:

738 1. *Data*: For the exchange of data. Like SDMX-JSON, SDMX-CSV can include both  
739 code IDs and labels which is helpful when using the data to create human readable  
740 charts and dashboards.

741

742 2. *Metadata*: For the exchange of reference metadata sets.

743

### 744 **5.4 Formats and Messages Deprecated in Version 3.0**

745 The following formats and messages have been deprecated in version 3.0 to simplify,  
746 modernise and rationalise the standard.

747

748 • SDMX-EDI

749 • SDMX-ML 1.0/2.0 Generic (time-series) data message

750 • SDMX-ML 1.0/2.0 Compact (time-series) data message

751 • SDMX-ML 1.0/2.0 Utility (time-series) data message

752 • SDMX-ML 1.0/2.0 Cross-Sectional data message

753 • SDMX-ML 2.1 Generic (Time Series) data messages (for observations, time-series and  
754 cross-sectional data)

755 • SDMX-ML 2.1 Structure Specific Time Series data message

756 The following messages were deprecated in version 3.0 as a consequence of the deprecation  
757 of the SOAP web services:

758 • SDMX-ML Query messages

759 • SDMX-ML Submit Structure Request messages

760

## 761 **6 Dependencies on SDMX content-oriented guidelines**

762 The technical standards proposed here are designed so that they can be used in conjunction  
763 with other SDMX guidelines which are more closely tied to the content and semantics of  
764 statistical data exchange. The SDMX Information Model works equally well with any statistical  
765 concept, but to encourage interoperability, it is also necessary to standardize and harmonize  
766 the use of specific concepts and terminology. To achieve this goal, SDMX creates and  
767 maintains guidelines for cross-domain concepts, terminology, and structural definitions.  
768 There are three major parts to this effort.

### 769 **6.1 Cross-Domain Concepts**

770 The SDMX Cross-Domain Concepts is a content guideline concerning concepts which are  
771 used across statistical domains. This list is expected to grow and to be subject to revision as  
772 SDMX is used in a growing number of domains. The use of the SDMX Cross-Domain  
773 Concepts, where appropriate, provides a framework to further promote interoperability  
774 among organisations using the technical standards presented here. The harmonization of  
775 statistical concepts includes not only the definitions of the concepts, and their names, but  
776 also, where appropriate, their representation with standard code lists, and the role they play  
777 within data structure definitions and metadata structure definitions.

778  
779 The intent of this guideline is two-fold: to provide a core set of concepts which can be used  
780 to structure statistical data and metadata, to promote interoperability between systems  
781 (“structural metadata”, as described above); and to promote the exchange of metadata more  
782 widely, with a set of harmonized concept names and definitions for other types of metadata  
783 (“reference metadata”, as defined above.)

784

### 785 **6.2 Metadata Common Vocabulary**

786 The Metadata Common Vocabulary is an SDMX guideline which provides definition of terms  
787 to be used for the comparison and mapping of terminology found in data structure definitions  
788 and in other aspects of statistical metadata management. Essentially, it provides ISO-  
789 compliant definitions for a wide range of statistical terms, which may be used directly, or  
790 against which other terminology systems may be mapped. This set of terms is inclusive of  
791 the terminology used within the SDMX Technical Standards.

792

793 The MCV provides definitions for terms on which the SDMX Cross-Domain Metadata  
794 Concepts work is built.

### 795 **6.3 Statistical Subject-Matter Domains**

796 The Statistical Subject-Matter Domains is a listing of the breadth of statistical information for  
797 the purposes of organizing widespread statistical exchange and categorization. It acts as a  
798 standard scheme against which the categorization schemes of various counterparties can be  
799 mapped, to facilitate interoperable data and metadata exchange. It serves another useful  
800 purpose, however, which is to allow an organization of corresponding “domain groups”, each  
801 of which could define standard data structure definitions, concepts, etc. within their domains.  
802 Such groups already exist within the international community. SDMX would use the Statistical  
803 Subject-Matter Domains list to facilitate the efforts of these groups to develop the kinds of  
804 content standards which could support the interoperation of SDMX-conformant technical  
805 systems within and across statistical domains. The organisation of the content of such  
806 schemes is supported in SDMX as a Category Scheme.

807

808 SDMX Statistical Subject-Matter Domains will be listed and maintained by the SDMX Initiative  
809 and will be subject to adjustment.

## 810 **6.4 SDMX Concept Roles**

811 These guidelines define the standard set of SDMX Concept Roles and their use. This set of  
812 standard SDMX Concepts are implemented as a cross-domain Concept Scheme that defines  
813 the set of concept roles and gives examples on concept role implementation in SDMX 2.0,  
814 2.1 and 3.0. A concept role gives a particular context to a concept for easy and systematic  
815 interpretation by machine processing and visualization tools. For example, the concepts  
816 REPORTING\_AREA and COUNTERPART\_AREA are different concepts but they are both  
817 geographical characteristics, therefore they can be associated with the same concept role  
818 ID: "GEO". This allows visualization systems to interpret these concepts as geographical data  
819 in order to generate maps. The implementation of concept roles is different in versions 2.0  
820 and 2.1/3.0 of the SDMX technical standard. Specifically for SDMX 3.0, this set of roles is  
821 considered a normative list that must be interpreted in the same way by all organisations.  
822 Additional roles may be provided via the standard roles' mechanism in SDMX 3.0, i.e., via  
823 Concept Schemes; the semantics of these roles have to be agreed bilaterally in data  
824 exchanges. The Concept Roles are available as an SDMX Concept Scheme on the SDMX  
825 Global Registry.

## 826 **7 Validation and Transformation Language**

827 For many years the SDMX initiative has been fostering and supporting the development of a  
828 standard calculation language, called Validation and Transformation Language (VTL). A  
829 blueprint for defining calculations was already described in the original SDMX 2.1  
830 specifications (package 13 of the Information Model - "Transformations and Expressions"). It  
831 was just a basic framework that required further developments to become operational in order  
832 to achieve a calculation language able to manipulate SDMX artefacts.

833

834 These developments started in late 2012 and were put in charge of the Validation and  
835 Transformation Language Task Force (VTL TF), which included members of the SDMX  
836 Technical Working Group (TWG) and Statistical Working Group (SWG), besides experts  
837 coming from the DDI and GSIM communities. The intent was to define a standard language  
838 to be implemented in SDMX and applicable also to GSIM and DDI. This brought to the  
839 publication of the VTL 1.0 in 2015. Then new requirements came from a number of proofs of  
840 concepts and tests of VTL 1.0 made by several organisations and triggered a large  
841 improvement of the language. A new provisional version, the VTL 1.1, was released in public  
842 consultation in 2017. The high number of comments received triggered another phase of  
843 intensive work, with the main goal of achieving a more robust and forward compatible version.  
844 Finally, the VTL 2.0 was published between April and July 2018 (see the SDMX website).

845

846 The implementation of the VTL 2.0 in SDMX started in late 2018 and was published as an  
847 incremental revision to the SDMX 2.1 standards in July 2020. It allows users to write VTL  
848 2.0 programs for validating and transforming SDMX data, to store these programs in a SDMX  
849 metadata registry and to exchange them through SDMX messages, also together the  
850 definition of the data structures of the involved data.

851

852 The Transformations and Expressions package for modelling VTL programs in the SDMX  
853 information model is explained in Section 2 of the Technical Specifications with further  
854 detailed usage and implementation guidance given in Section 6.
